1987

VOLUME II

The Growth of Industrial Societies and Capitalist Economies

Preface	5
Introduction	7
VI Population and Families	15
Chapter 1: Population growth	17
Chapter 2: Marriages and families	145
VII Urbanization and Housing	245
Chapter 3: Cities and urbanization	247
Chapter 4: Housing conditions	283
VIII Economic Growth	335
Chapter 5: Growth of national product	337
Chapter 6: Origin and use of national product	401
IX Division of Labour and Inequality	441
Chapter 7: Labour force	443
Chapter 8: Income distribution	611
X Trade Unions and Strikes	675
Chapter 9: Trade unions (missing)	677
Chapter 10: Labour disputes	679
A note on documentation	755

VOLUME I

The Growth of Mass Democracies and Welfare States

Preface

Introduction: Stein Rokkan's Macro-Model of Europe

I National States

- Chapter 1: Territories and citizens
- Chapter 2: Cultural heterogeneity

II Mass Democracies

- Chapter 3: Suffrage and elections
- Chapter 4: Parliaments and coalitions

III Personnel of the State

- Chapter 5: Government personnel
- Chapter 6: Military personnel

IV Resources of the State

- Chapter 7: Public revenues
- Chapter 8: Public expenditure

V Welfare States

- Chapter 9: Income maintenance
- Chapter 10: Public education

Tempus fugit. When I finished the preface to the first volume of our handbook in 1982, it was summer and I was still living in Florence. The magic of Tuscany may have deluded my mind. I thought that we would be able to finish the second volume within a year. We were not. It is now almost Christmas in the winter of 1985. I am surviving in Mannheim, and Tuscany's magic has long since disappeared in the cisalpine clouds. Is there a convincing explanation for this delay which caused our publisher so much despair? There is none, at least I can't find one, or there are too many.

Among the many reason, the most important was the decision by Franz Kraus and Winfried Pfenning to establish a completely new data collection on the structural change of the labour force, based on more than a hundred population and occupational census. This great endeavour was only the last step in raising their former status of near slavery in the first volume to full authorship in the second. However, their merits go far beyond this.

Franz Kraus was also responsible for the two chapters on the growth, origin and use of national product, which he finished more than five years ago. Furthermore, and this will be his *opus magnum*, he has created a unique collection of historical data on income distribution drawn from tax statistics. The chapter in this volume contains only a part of this collection. An analysis of the whole data set will be published in 1986 as a separate study within the series 'European Social Science Studies' at Campus Verlag.

Winfried Pfenning was responsible for the chapter on labour disputes (which he finished), as well as the chapter on trade unions (which he did not finish). He deserted academia for commercial market research in the summer of 1985, I can't blame him. A completion of his chapter on trade union development would have held up the publication of the second volume for at least another six months. Therefore, we decided to drop it. This is unfortunate, not only for reasons of substance, but also for reasons of symmetry. The second volume now has only nine chapters instead of ten.

However, one must do Winfried Pfenning justice. He was responsible for the computerization of our data sets and laid the basis of the machine-readable documentations. For three years this work was funded by the Stiftung Volkswagenwerk. Once again, I take the opportunity to thank the foundation for its manifold support of our projects. I also extend my thanks to the students who assisted Winfried Pfenning when he worked at the Zentralarchiv in Cologne: Sofia Bengel, Irene Bolz, Hannelore Burmann, Annekatrin Gehring, Rolf Knepperger and Sabine Rest.

The first four chapters have a long and confusing history. Parts of them were finished successively in Mannheim (1973–76), Cologne (1976–79), Florence and Cologne (1979–82) and again in Mannheim (1982–85). All those who have made contributions to the earlier phases have been credited in the preface to the first volume. Here I should mention again Kurt Seeböhm who has contributed much to the data collection on population and family movements. And I should also again thank the central archive of the ICPSR at Ann Arbor for helping us in the computerization of our complex tables on population structure, a work which was largely completed in Cologne (1979–82).

In the last years in Mannheim, a whole battalion of students has worked on the completion of the chapters on urbanization and housing, the labour force and labour disputes. I would like to thank Bernhard Ebbinghaus, Katrin Behagel, Reinhard Goehrtz, Thomas Huber, Uwe Keil, Klaus Mayer, Klaus Overhoff, Elmar Rieger, Michael Schönenmann, and Siegbert Sussek (who also made the graphs). I am most indebted to the two Ursulas who typed most of the tables, Ursula Nocentini at the European University Institute and Ursula Rossi at the University of Mannheim. Last not least, I wish to thank Margaret Herden for her attempt to split unreadable German sentences into more comprehensible English phrases.

Let me finish with a sigh of relief and an oath: NEVER AGAIN!

The two volumes of the handbook

The structure and contents of the first volume of this historical data handbook are closely related to Stein Rokkan's macro-model of Europe in which he tried to develop a systematic account of the major variations among the European nation-states. Of the four phases of political development which he distinguished, *the growth of mass democracies and welfare states* form the core of the first volume. Due to limitations of available data, the other two processes of state formation and nation-building, which in the European context predated the institutionalization of political and social rights, are dealt with to a far lesser extent.

That political development in Europe would lead to a system of nation-states was not evident at the beginning. If one follows Charles Tilly (1975), then the nation-state represented only one of five possible paths of development in the thirteenth century; the others being the persistence of feudalism, the evolution of an embracive trading network, and the creation of a political or a theocratic empire.

Today, we know of course that the nation-state finally triumphed: a relatively centralized political system with a consolidated territory, differentiated political structures and a monopoly of the legitimate use of force. It triumphed for several reasons. Most important were probably the political fragmentation of Europe and the openness of her periphery, but also early capitalism, the growth of cities, commerce and manufacturing, which offered the resources for centre building and state formation.

It took some time, however, to triumph; at least until his sixteenth century when the Hapsburgh failed to consolidate their empire. According to Wallerstein (1974), this failure was an essential precondition for the emergence of a capitalist world-economy which none of the emerging nation-states could control.

A world-economy, in Wallerstein's understanding, is one of two types of world-system which he defines in terms of a relatively closed division of labour and plurality of cultural systems. In contrast to a politically unified world-empire, a world-economy embraces several political systems. In a capitalist world-economy, production is predominantly oriented towards market exchange, and profit becomes the driving force in quantitative expansion and qualitative improvement. It is furthermore characterized by labour becoming a 'commodity', i.e. by the extension of a labour market, in contrast to a system in which the owners are mainly small farmers and artisans.

What one today calls modernization, started in Europe in the context of an international system of nation-states and a capitalist world-economy. This framework has shaped the European development, and with Europe's expansion it has left its imprint on other world regions. Thus the nation-state, although hardly achieved anywhere, is still the predominant model of political development. And the position of the newly independent states in the international division of labour — a structure of dependence and inequality — sets limits to the options open for national development.

At the same time, however, we have learned today that there are more paths to modernity, more ways to build industrial and urban societies, than those suggested by European experience. 'Capitalist development' or even 'capitalist-democratic development' is only one form of modernization, and history has certainly not yet exhausted the combinatorics of modern institutions. Beyond the variations in basic political and economic institutions, however, all modern or modernizing societies share many fundamental characteristics. This combination of uniformity and variety is expressed by the title of the second volume of the handbook '*The growth of industrial societies and capitalist economies*'.

When Tocqueville wanted to know more about the future of France he went to study American democracy. When Marx wished to understand more about the future of Germany he began to study English industrial capitalism. They could do this only because both of them had concepts of a *general* development, different as these were. But Tocqueville was a little more prudent. Not only was he aware of the unique features of American democracy, he also conceived of alternative developments of democracy, pluralistic and totalitarian as we would call them today. Marx, on the other hand, cared less about the unique features of English capitalism, and he did not conceive of forms of non-bourgeois or even non-capitalist industrialization.

Marx' reliance on England as exemplifying capitalism made him underestimate the role of the state in capitalist development. His conception of capitalism as a general and necessary stage of development gave him no reason to distinguish between 'capitalism' and 'industrialism'. Marx was primarily interested in the class character of capitalist societies, based on the institutions of private property and wage labour; and he was interested in the logic of capitalist development, as shown in the process of capital accumulation and endemic crises of overproduction. From this point of view 'industrialism' is important only insofar as the existence of a capitalist society presupposes a high level of industrialization.

The reverse, however, does not hold true. For this we should not blame Marx too much, because at the time when he was writing there was no example of non-capitalist industrialization. Even after the Russian Revolution and the accelerated industrialization of Russia in the 1930s, it took a long time until a clear distinction was drawn, first perhaps by Raymond Aron in his famous lectures on the industrial society of 1955 (1962). For Aron 'industrial society' is the general type of modern society, and he distinguishes subtypes by the form of ownership of the means of production and by the basic allocation mechanism. Accordingly, predominantly private ownership, wage labour and the division between employers and employees, profit orientation as crucial momentum, and decentralized allocation via the market, are the essential characteristics of 'capitalist societies'. To these Aron adds the openness of the national economy vis-a-vis the world economy with the resulting pressures of adaptation, the decisive influence of consumer decisions on the distribution of resources, and the existence of free trade unions.

These capitalist societies share, however, certain features with other industrial societies. Aron emphasizes above all the accumulation of capital and the concentration of the workforce, the high level of economic rationality, the extended division of labour within enterprises, and the separation of family and workplace. He also mentions the expansion of formal education, the importance of science and technology, the bureaucratization of production, the increase of dependent labour, and the regulation of work and work life. In this sense 'industrialization' has a standardizing impact on the social structure of modern societies, although differences in class structures and other aspects clearly persist. This limited convergence with respect to social structure, however, does not in Aron's view imply a convergence in politics, of democracy and dictatorship.

After Aron, and mainly under the influence of American sociology, the concepts of 'industrial society' and 'industrialization' were largely replaced by 'modern society' and 'modernization'. This was necessary, although it has not contributed much to the clarification of concepts. It was necessary, because the broad changes which European societies underwent for more than two hundred years and which other societies undergo today, cannot merely be interpreted as preconditions, implications or consequences of industrialization in a stricter sense. It has created conceptual confusion, because for a long time the uniformities of the modernization process were overstressed. This led to a neglect of the alternative paths to modernity which spring from differences in inherited institutions as well as from changing external conditions.

The vital revolution and demographic transition

The secular increase of Europe's population from the second quarter of the eighteenth century was a revolution, but not a completely new phenomenon. In fact it represented the third major upswing in European population history, the first extending from the middle of the eleventh to the end of the thirteenth century, and the second from the middle of the fifteenth to the end of the sixteenth century. The third upswing was initially caused by a release from the population constraints associated with war and epidemic, and by considerable improvements in agricultural production and commerce.

Although population increase predated the Industrial Revolution in a stricter sense, it was this later process which transformed the third upswing into the Vital Revolution. This time the upward movement not only started from a higher level, but it was able to maintain, and for some time even to increase its momentum. Unlike the previous upswings, population growth was not terminated or reversed by catastrophes but was eventually slowed down by a change of the basic 'generative structure'.

The demographic revolution was broadly synchronized with the spread of industrialization and the shift from rural to urban life. In the nineteenth century improvements in the quality of food, shelter, clothing, water supply and sanitation gradually brought about a reduction in death rates, this reduction being accelerated after 1900 when modern medical science began more systematically to contain infectious disease and reduce infant mortality. This decline in death rates outweighed the usually later decline in birth rates, giving rise to a population surge which culminated in the period from the late nineteenth century to World War I.

In most instances fertility had already begun to decline in the nineteenth century and showed an irregular but generally downward trend from the turn of the century. Upsurges in birth rates after 1918, in the late 1930s, and after 1945 did little more than compensate in some measure for birth deficits associated with war and depression. For the first time, during the depression of the 1930s net reproduction rates (which measure the future reproduction of the population on the basis of the current rates of fertility and mortality) fell below the level of 1.00. After World War II, however, there was a widespread increase of birth rates, and it was not until the 1960s that they started to decline again, bringing net reproduction rates to even lower levels.

Europe's demographic development has formed the empirical basis for a generalized 'theory of demographic transition' which essentially states:

1. Pre-industrial societies are characterized by high levels both of fertility and mortality. Because of high fertility populations are young and because of high mortality population increase is small. Fertility generally is higher than mortality, but population growth is frequently checked by catastrophic mortality. This is due to the extreme vulnerability of pre-industrial societies to calamities of all sorts which makes epidemics in particular a regulatory device.
2. Fully industrialized and urbanized societies instead are characterized by low levels both of fertility and mortality. Because of low fertility populations are old and population increase is small or even negative. Due to the higher adaptive capacities of these societies mortality fluctuates only moderately whereas fertility is more volatile.
3. The demographic transition from high to low levels of fertility and mortality is characterized by a time-lag between the decline of mortality and the decline of fertility. This produces a high rate of natural population increase as a transient phenomenon. The reason for this time-lag is assumed to be that industrialization has a more immediate impact on mortality whereas a decline of fertility requires far more complex changes in social structure which ultimately are also produced by the process of modernization.

In terms of this simplified model one can specify some features of the demographic transition which are peculiar to Europe in comparison to the late-comers among the modernizing countries: a much slower and more gradual decline of mortality because of the later impact of modern medicine; a generally lower fertility because of a specific 'European marriage pattern'; as a consequence, a comparatively lower natural increase of population with demographic pressures further eased by the exceptional opportunity of intercontinental migration (between 1846 and 1932, according to Carr-Saunders (1936), more than 50 million Europeans emigrated overseas).

The first and last features speak for themselves, but the second needs some explanation. There is a distinctively (North-Western) European marriage pattern which can be traced back to the seventeenth century and which existed up to World War II. Its distinctive marks are (a) an advanced age at marriage and (b) a high proportion of people who never married (Hajnal 1965). This pattern was related to a specific household system in which the great majority of households were nuclear-family households which did not contain relatives, but which included life-cycle servants (i.e. young women and men who lived in the household of their masters).

Malthus thought that late marriage in Europe resulted in lower birth rates, as one of the 'positive' or 'negative' checks which would appear when population transcends its 'optimum size' and approaches a certain 'ceiling'. His model of development was formulated in terms of fixed land and population growth. Whereas the 'passion between the sexes' makes population grow in 'geometrical progression', food supply

only increases 'arithmetically'. With the supply of free land exhausted, the law of diminishing returns leads to a decline in labour's marginal product. This means a fall in living standards which in turn produces the above checks to population growth.

Ironically, Malthus, bound to traditional Europe, developed his gloomy futurology at a time when the technological process was beginning to invalidate the law of diminishing returns by constantly raising labour's productivity. Thus, by contrast with Malthus' theory of stagnation, Kuznets (1966), the great pioneer in the development of historical national accounting systems, regards population and economic growth as being closely related. He understands modern economic growth as a sustained increase in per capita or per worker product, most often accompanied by an increase in population and usually by sweeping structural changes.

The urban and industrial revolutions

Modern economic growth, according to Kuznets, is characterized by rates of increase in per capita product which range from less than 15 to about 30 percent per decade. Assuming a rate of population growth of about 10 percent per decade, this means an enormous growth of total output ranging from 20 to close to 50 percent per decade.

Sustained economic growth of these proportions was only made possible by the Industrial Revolution, the most dramatic of all revolutions in world history. In a narrow sense, the Industrial Revolution was a process by which societies acquired control over vast sources of inanimate energy. But such a definition does not do justice to the complex economic, social, political and cultural implications of this phenomenon. Kuznets therefore stresses that the rate of increase in per capita product was not primarily due to quantity of input, but to improvements in quality, i.e. increases in useful knowledge and better institutional arrangements for its utilization. Furthermore, the growth in efficiency was not only rapid but also pervasive. This means that the industrial revolution was preceded and accompanied by an agricultural revolution and by a striking increase in the capacity of transportation and communication.

The Industrial Revolution occurred in England because of a specific constellation of historical circumstances, and from England it soon spread to the rest of Europe. By 1850 it had penetrated into Belgium, France, Germany, and Switzerland; by 1900 it had extended to Northern Italy and Scandinavia. Until the entry of Japan in the late nineteenth century, followed by the U.S.S.R. in the 1930s, modern economic growth was concentrated in the European countries and their offshoots overseas. In these countries per capita incomes were well above the average even before industrialization.

The Industrial Revolution gave Europe a tremendous advantage over the rest of the world, founding its world-wide predominance in the nineteenth century. But even within Europe, the different timing of industrialization or of the economic take-off as W. W. Rostow has called it, meant great inequalities in the rate of aggregate growth which often cumulated in marked shifts in relative economic and political power among the European nations.

Beyond the creation of new inequalities between countries, however, modern economic growth in general strengthened the interdependence between nations, in terms of the international flow of men, goods and capital. This is especially true for the period from the second quarter of the nineteenth century up to 1914. World War I radically changed these international flows. International migration has never resumed pre-1914 levels, whereas the flow of goods and capital did, but only after World War II.

Internally, modern economic growth produced a basic transformation of social structure. Two broad changes were especially important: the marked and rapid changes in industry, status and occupational structures of the labour force; and the great increase of mobility in its various forms, the occupational shifts within and between generations and the considerable migration within countries, urbanization being the most important form.

Urbanization is not the same as urban growth. Cities have a history of almost ten thousand years which is closely related to the creation of large political structures, the growth of great religious cults, and the expansion of trade. Urbanization, on the other hand, is a much more recent phenomenon. In its simplest ecological meaning it is an increase in the proportion of the total population of an area which is living in cities. Before the Industrial Revolution there was no country with much more than a tenth of its population living in cities, and few cities had more than a million people. Up to the mid-nineteenth century no society could be described as predominantly urbanized.

It is a curious fact that urbanized societies arose in a region, North-West Europe, which had not given rise to the major cities of the past. However, this region has given birth from the tenth and twelfth centuries onwards to a unique form of city. The cities of Medieval and Renaissance Europe had something essentially different from towns in other world regions. They were autonomous organisms, clearly separated from the surrounding countryside, the core of new social and political structures, of a new culture and a new economy.

At a certain point, however, these cities, founded on guilds and corporations, became an obstacle for an inter-urban restructuring of economic life. Thus, the current wave of urbanization started much later, around 1700, with the emergence of national states and the extension of the capitalist world economy. It developed into a truly revolutionary process through its connection with the later industrialization.

Industrial urbanization differs from other forms of urbanization not only in terms of pace, scale and thoroughness, but also in quality. It does not produce a city structure as a specific social form. The city instead tends to lose its different structural and cultural characteristics: it tends to coincide with global society. This is mainly due to the technological implications of the increasing division of labour. These have centralizing as well as decentralizing consequences, leading to urban concentration as well as geographical diffusion.

Modern urbanization thus is best understood in terms of its connection with economic growth. As Kingsley Davis (1974) has put it, urbanization is a finite cycle through which nations go in their transition from agrarian to industrial society and which can be represented by a curve in the shape of an attenuated S. However, even if this curve is similar for all modernizing countries, in comparison to the latecomers, urbanization in Europe had at least two specific marks: its pace was much slower and its connection with industrialization much closer.

Until the nineteenth century, Europe was agricultural and rural. Within a century it became industrial and urban. This long-term transformation is often described in terms of a sequence of different types of societies: a traditional society in which agrarian work predominates, an industrial society characterized by manufacturing, a post-industrial society in which service work prevails. Clark and Fisher were the first to analyze this development in terms of a sectoral change of the labour force. Somewhat later Jean Fourastié (1963) tried to incorporate these changes into a broader concept of a transitional period between a stable 'primary civilization' of the past and a stable 'tertiary civilization' of the future.

It is technological progress which destroys the traditional balance. It increases the productivity of capital and labour, but these productivity gains vary among economic sectors (being high in the 'secondary', medium in the 'primary', and low in the 'tertiary' sector). Because the elasticity of demand also varies among sectors (being low in the 'primary', medium in the 'secondary', and high in the 'tertiary' sector), intersectoral differences in productivity increases lead to a change in the structure of demand, and thus to a change in the structure of production, and ultimately to a change in the structure of employment.

Given these intersectoral differences, technological progress, according to Fourastié, produces the following:

- a steady decline of employment in the primary sector, essentially agriculture, in form of an inverted attenuated S, from almost 80 percent to maybe less than 5 percent;
- a steady increase of employment in the tertiary sector, basically all varieties of services, in a kind of mirror-image of the decline of agricultural employment;
- a transient increase in industrial employment, starting slowly, then accelerating in the 'expansion period' up to a maximum of say 50 percent, after which it begins to decline again, flattening out at the end at a much lower level.

The transitional period therefore is marked by the rise of industry to predominance, and by its subsequent relative decline. For Fourastié, this is a period of economic, political and social instability. The traditional crises of agricultural underproduction are replaced by crises of industrial overproduction with recurrent mass unemployment. The rapid and thorough changes in the structure of the labour force generate anomie, lead to a mobilization of large population groups, and create political conflicts and crises.

In a recent work, however, Hartmut Kaelble (1983) has shown that a pronounced period of industrial society can only be found in Europe. The modernization of advanced non-European societies was characterized instead by a direct transition from an agrarian to a service society. Only in Europe was industrial work the most dynamic sector of employment from the nineteenth century until recently, and even now the move towards a service society seems to be less marked than abroad. The explanation which Kaelble offers for this

— once more — unique European development lies, above all, in the high exportation of manufactured goods from Europe to the world market and in the labour intensive industrialization of Europe. The longstanding predominance of a large and homogeneous industrial working class has certainly contributed a great deal to the interpretation of European modernization as the emergence of class society.

The rise and subsidence of class society

One can define class in such a generic way that the term applies to all societies in human history which have surpassed the subsistence level and have a certain division of labour. In these societies the control of the means of production may be crucial in the structuring of social inequality. It seems more useful, however, to interpret class society as a modern phenomenon which emerged in Europe from the ruins of feudalism. The extension of markets in general and of the labour market in particular, was a precondition for the emergence of class society. Capitalism had to destroy the legally sanctioned differentiation between estates, the feudal bonds and personalized ties of fealty, and the relatively self-sufficient character of local communities.

In this perspective, class society is something essentially different from estate society. It is founded upon the differentiation of two institutional spheres, commerce and industry on the one hand and the state on the other, thus breaking up the old fusion of economic and political power. Classes are defined as large-scale (national or even international) groupings of nominally free persons who have a common relation to the means of production, and occupy a similar position in the division of labour and market exchange. They do not necessarily have a sense of identity, a common class consciousness or class organization.

Our understanding of the long-term change of class structures has been shaped again and again by the arguments of, with, and about Marx. This is not the place to repeat — yet again — his basic ideas. In one way he had a very clear view of the future development, namely that capitalism would lead to a concentration of productive capital in the hands of fewer people and that the share of dependent work would steadily increase. In another way, however, he was rather misled, namely that in the long run capitalist development would produce a much more simplified class structure and an increasingly clear-cut and overt class conflict. The contrary is true: today, the class structure is more complex than ever, and class conflict has become more diffuse and simultaneously more institutionalized.

In order to overcome sterile disputes about the existence of class society, Anthony Giddens (1973) has suggested that we speak about types and levels of class structuration, an idea derived from Weber's class analysis. For Weber a class structure is a specific form of social inequality in which life chances are essentially determined by market position. In this sense market position is class position. There can be a great variety of different market positions and therefore a plurality of classes, the two most important dimensions being property (ownership classes) and qualification (acquisition classes). The whole spectrum of classes may be more or less structured, according to Weber, depending on the extent of inter-class mobility. Class structuring will also depend, Giddens adds, on the typical division of labour and the authority structure in enterprises as well as on differentiations in the sphere of consumption.

The complexity of this concept emphasizes the difficulties involved in a systematic empirical analysis of the long-term change of class structuration in the process of industrialization. Especially as regards the distribution of property, social mobility, work and authority relationships in enterprises or consumption patterns, one has to rely mainly on case studies which never give a complete picture.

To some extent this is also true for the distribution of educational and vocational qualifications among the population, although in this case one can use — at least indirectly — the available information on the evolution of the national education systems. There can be little doubt that the extension of secondary and higher education has changed the form and extent of class structuration: by the upgrading of market capacities — in the form of 'human capital' — of broader population groups on the one hand, and by creating greater differences among the employed labour force on the other.

In principle, both tendencies must be reflected in the distribution of income, strengthening the middle income strata and differentiating income from dependent work. We certainly do not know enough about long-term changes in income inequality at the national level, as our information is dependent upon the — relatively late — introduction of national income taxation. Some broad trends, however, seem to be con-

firmed by existing studies (Kraus 1981). Changes in the top income strata seem to have been decisive for the trend in overall income inequality. The relative decline of top incomes appears to have been a general development, starting perhaps in the late nineteenth century and being most evident during both world wars. It is probable that all other income groups have gained to some extent from this relative decline, but the middle groups seem to have profited the most.

European societies have become less class structured because market positions seem to be more differentiated and market capacities more continuously distributed. They are also less class structured in the sense that today individual life chances are less determined by market position. Material welfare is much less dependent on market income. Direct and indirect taxes, transfer payments, and the provision of public services have clearly reduced the importance of wages and assets in determining economic status.

It is not unlikely that the initial phase of European industrialization was marked by an increasing class structuration (Kaelble 1983). But since the turn of the century this — real or presumed — trend has been reversed. The long-term process of class de-structuration has been paralleled by an increasing organization and institutionalization of class conflict. In a very broad sense, this refers to the evolution of mass democracies which has frequently been interpreted as an institutionalization of class conflict, leading to the creation of welfare states. In a stricter sense, however, it refers to the establishment of trade unions and recognized forms of collective bargaining.

The trade unions, the second major pillar of the working class movement, developed throughout Europe as a product of the industrial revolution. However, the countries responded in very different ways to this general development. Reinhard Bendix (1964) has distinguished three broad types of policies. The Scandinavian and Swiss type can be characterized as a modernization of the traditional organization of crafts, allowing for a high degree of continuity and a low degree of repression. The absolutist type instead represented a major break with the traditions of liberty as a corporate privilege, leading to the repression of all sorts of associations. In the liberal type exemplified by England, workingmen's associations were also suppressed, but the right of association was preserved in other respects. Thus, the political and institutional frame work of trade union development greatly varied across Europe.

Trade unions were first organized by highly qualified groups in certain crafts with remnants of a 'guild spirit'. The *raison d'être* of these craft unions was not only to organize strike support, but also to provide social security on a mutual benefit basis and to monopolize qualified labour. The first national craft unions were established in the last third of the nineteenth century, and this process was largely concluded on the eve of World War I. The foundation of national trade union federations started at about the same time, culminating around the turn of the century.

The formation of industrial unions according to the principle of 'one establishment — one union' was a basic goal of national trade union federations everywhere, but the success with which the unions pursued this goal has greatly varied. To some extent, these variations are explained by differences in the early development of craft unions. This explains at least the major differences between the United Kingdom, Ireland and Scandinavia, where craft unionism still predominates, and the other countries where industrial unions were formed to a large extent. Some of the variations are also explained by later developments which have weakened the industry principle and furthered organization along status lines. The general change in the occupational structure, brought on by the growth of public and private bureaucracies and the emergence of new professions, has led to the formation of white-collar organizations in all countries, some dating back to the end of World War I. But again there are great variations in the form and the degree of the unionization of white-collar employees and civil servants.

Finally, one must also take into account the varying impact of rival political unionism on the structure of the trade union systems. Political cleavages were especially strong in the Catholic countries and the Protestant countries with a strong Catholic minority. Only in Austria and Germany, the cleavage between Catholic and socialist trade unions has been overcome. It persists in Belgium, France, Italy, the Netherlands and Switzerland, where unification attempts have largely failed. In several countries, the structure is further complicated by the varying splits between socialist and communist trade unions.

Differences in the organization of labour are closely tied to variations in strike patterns. Over the last hundred years the form and frequency of strikes has profoundly changed. According to Edward Shorter and Charles Tilly (1974) three great changes have occurred in virtually all Western European countries:

- secular increase in the rate of conflict during the last quarter of the nineteenth century and the first quarter of the twentieth century, followed by a large-scale decline during the 1920s and the Depression;
- a secular decrease in the duration of conflict starting around the Great Depression, and continuing after the Second World War;
- an increase in participation in strikes, sometimes beginning during the Great Depression, sometimes beginning just after the Second World War.

The user of this handbook will be able to check these statements on the basis of the data given in the concluding chapter of the second volume. They will not be able, unfortunately, to analyse the relationships between changes in labour disputes and the development of the trade unions. The chapter on trade unions is missing for reasons explained in the preface.

The other chapters are structured according to the outline given in this introduction. The second volume starts with two chapters in Part VI both of which are related to the demographic transition. They are followed in Part VII by two chapters on the process of urbanization and the changing housing conditions. The two chapters of Part VIII then give the essential data on economic growth, i.e. on the growth of the national product, its changing origin and use. These are followed again in Part IX by two chapters on the most important concomitants of economic growth, a changing division of labour and a changing economic inequality.

VI

Population and Families

POPULATION GROWTH

An analysis of the structure and change of larger populations requires that demographic data are collected in two ways. The first is a population census which is held at regular intervals, and the second is a continually operating vital registration system. In most European countries, these two instruments were developed in the nineteenth century, and in some countries they go back as far as the eighteenth century. Prior to this period one has to rely on more irregular and limited population counts, parish registers, or more indirect sources.

The earlier (e.g. Roman) 'censuses' were only partial population counts (heads of families, or that part of the population liable to taxation or military service), and must be supplemented by estimates of the non-enumerated portion of the total population. The first modern counts of total population were carried out in Renaissance Italy and Spain. Other European countries were relatively late in following suit: Norway in 1664 and 1701, Bohemia in 1702, Iceland in 1703, Austria in 1754, and Denmark in 1769. Sweden was the first country to institute a regular system of census taking in 1749. These, however, were not direct censuses but enumerations on the basis of population registers established at the same time. In 1790 the United States was the first to begin with a series of direct decennial censuses. Great Britain followed in 1801, and most European countries had adopted the practice by the mid-nineteenth century (see the following table).

The information recorded about each individual in a census varies from country to country and has been greatly extended over time. Only part of this collected information has been utilized for our handbook: Chapter 1 of this second volume presents data on the age and sex distribution of the population; chapter 2 on the civil status of the population by age and sex; and chapter 7 on the economically active population by industrial sector and occupational status. In the first volume of the handbook we presented census figures on total population and its distribution by nationality (chapter 1), and by religion, language, and literacy (chapter 2). Unless otherwise noted, these figures always refer to the *total resident population*.

The second main source of demographic data is the vital registration system, which normally includes marriages in addition to births and deaths. Here one must distinguish between ecclesiastical and civil registration. In some areas, parish registers kept by religious officials go back as far as the fourteenth century. In general, the recording of vital events received a strong impetus from the Reformation and Counter-Reformation with the attempt to register religious affiliation. The transformation of ecclesiastical into civil registration first took place in Northern Europe in the mid-eighteenth century. In most European countries civil registration started in the first half of the nineteenth century. In general, these civil registers (although not always beyond suspicion), are more reliable than their ecclesiastical predecessors.

A vital registration system allows us to study population change. Simple population change is divided into 'natural' changes (births and deaths), and 'mechanical' changes (emigration and immigration). The difference between births and deaths, commonly expressed per head of population, is called the natural increase (or decrease) of population. The well-known theory of demographic transition is formulated in terms of these three variables: the birth rate, the death rate, and the rate of natural increase of population. Chapter 1 therefore begins with a series of fifteen graphs which visualize the respective form of demographic transition for thirteen countries (the United Kingdom being subdivided into England and Wales, Scotland, and Ireland/Northern Ireland).

The statistics for these graphs are contained in the subsequent tables, in alphabetical order of countries. The three rates, expressed per thousand population, are based on the absolute figures of births, deaths and total population given there. In general, birth and death statistics are somewhat more reliable than total population figures. They are normally good for countries and periods with a need for birth and death certificates. Unless otherwise noted, total population figures refer to the *mid-year population*. Population figures (whether mid- or end-year) are usually calculated on the basis of the preceding population census, birth and

death statistics, and estimates of net migration (numbers of immigrants less emigrants). In some countries changes of address are registered, but normally under-registration is high and migration figures are far more unreliable than birth and death statistics. Official population figures are usually corrected on the basis of new population censuses retrospectively for the whole preceding inter-census period. These figures have been used here unless otherwise noted. In any case, errors in total population figures are of minor importance for birth and death rates, and consequently, for the rate of natural increase of population.

This is not true, however, for the population growth rate (defined here as the difference of total population in the years i and $i-1$, divided by the population in the year $i-1$, and multiplied by 1,000). It is obvious that errors in population estimates greatly influence this rate, as they do with respect to the net migration rate (here simply defined as the difference between the population growth rate and the rate of natural increase of population). The rates of both population growth and net migration should therefore be studied over a period of several years, and preferably for an entire intercensus period. Any interpretation of the net migration rates must furthermore take into account that the population growth rate refers to the change of *mid-year* population and the natural increase of population to the *calendar year*.

No attempt has been made to utilize statistics on emigration and immigration as these are generally rather unreliable and incomplete. More reliable statistics are only available for one prominent aspect of migration, the intercontinental emigration from Europe from the early nineteenth century until the 1930s. These can be found in A.M. Carr-Saunders' famous study (*World Population: Past Growth and Present Trends*, Oxford University Press, 1936), and are not reproduced here.

The calculation of crude birth and death rates is, of course, only a first and very simple step in describing the 'natural' change of population. For a more detailed analysis of the changes of fertility and mortality, these rates must be differentiated according to age, sex, marital status and other available criteria. More detailed fertility rates are given in chapter 2, in the form of a 'general marital fertility rate' (defined as the ratio of total legitimate births to total married female population aged 15–44 years), and the corresponding 'general non-marital fertility rate' (defined as the ratio of total illegitimate births to total non-married female population of the same age).

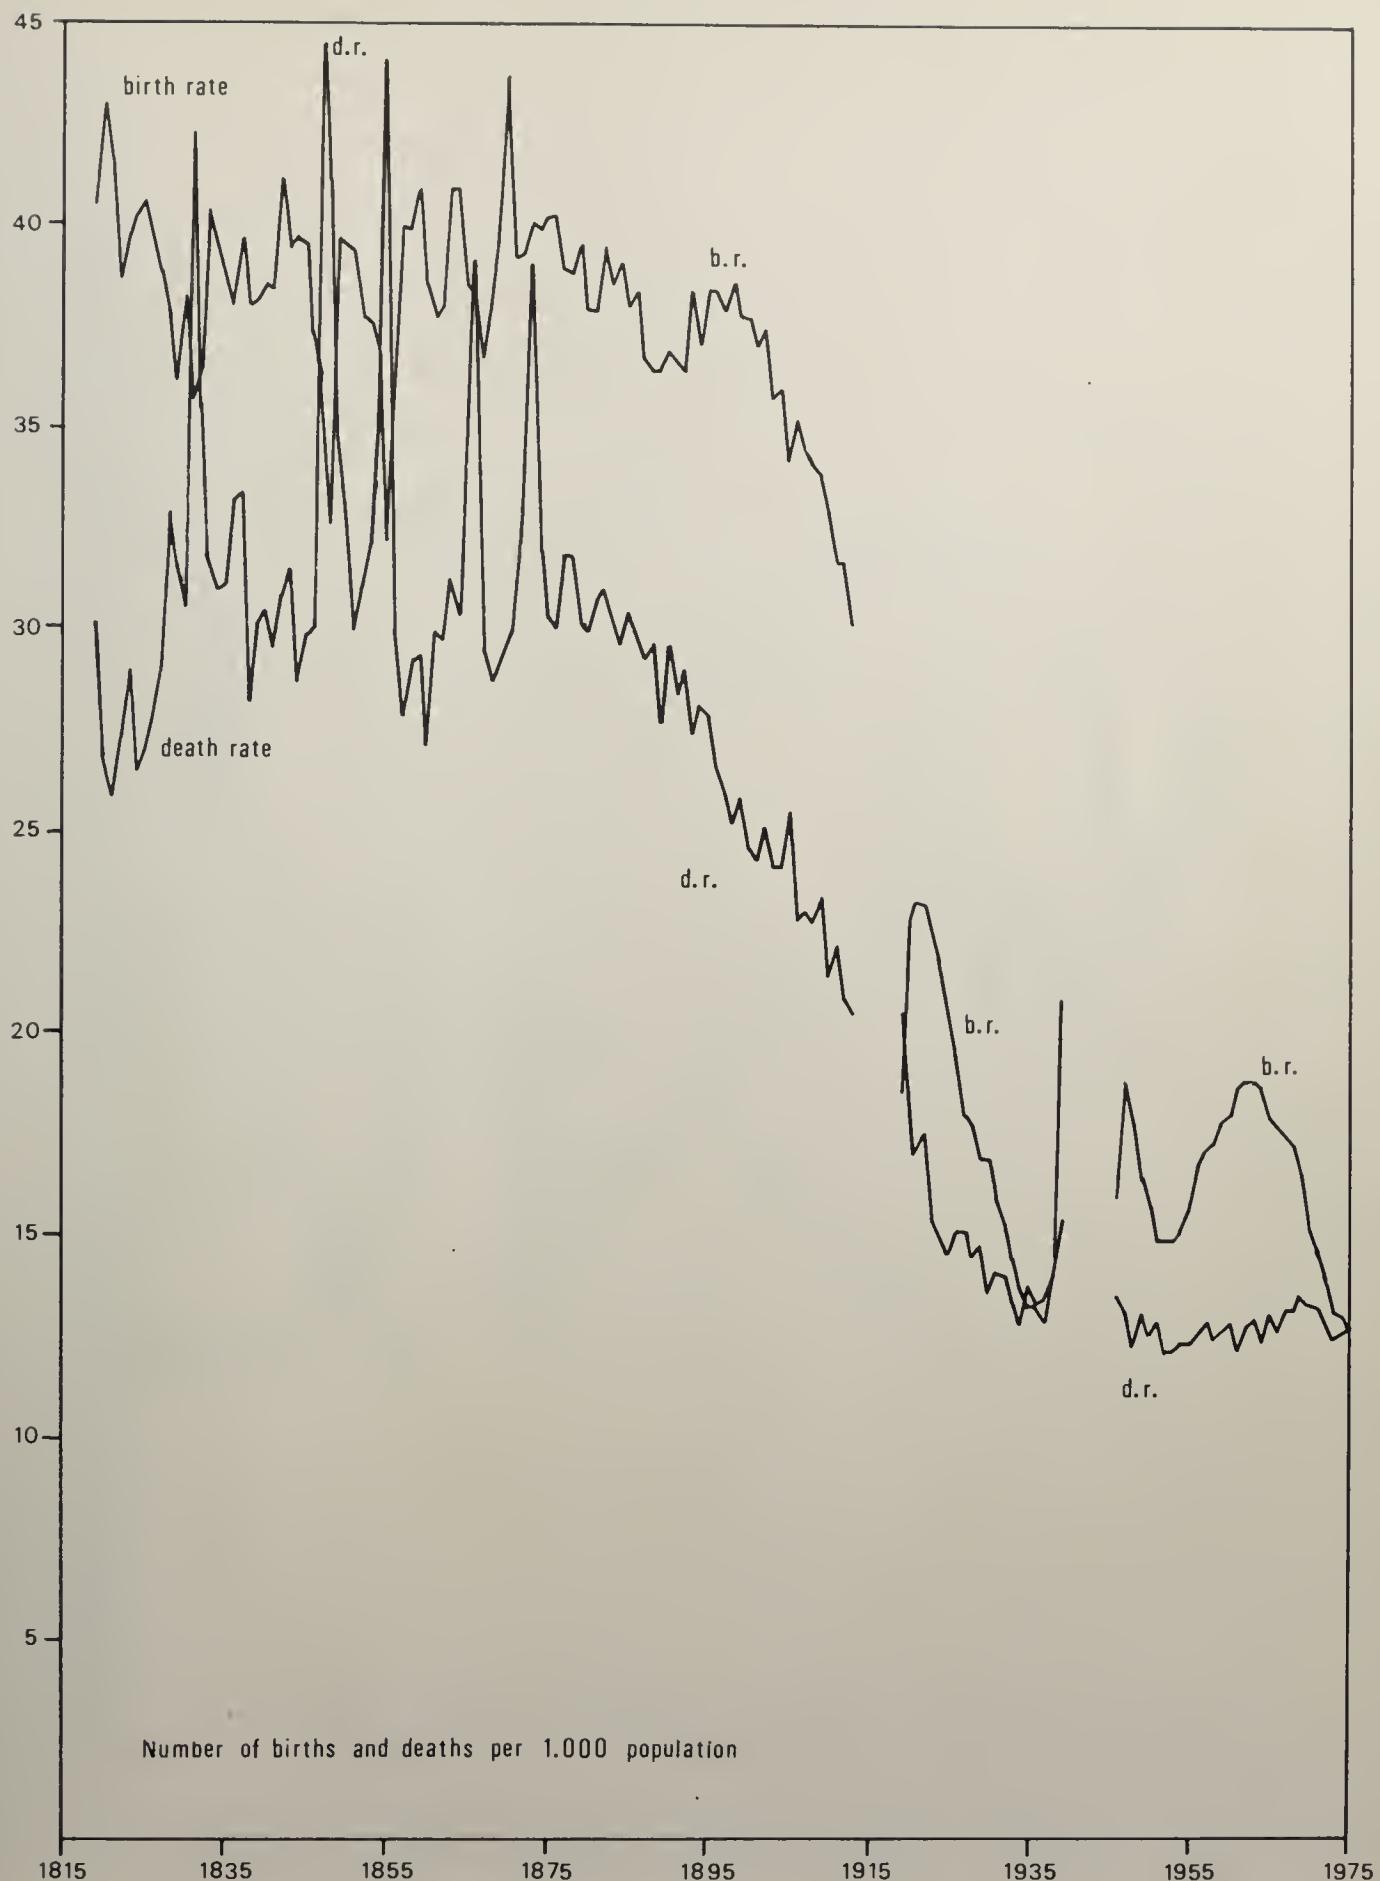

With respect to mortality, however, additional information is provided in chapter 1. The tables which contain the crude death rates also give infant mortality rates (defined as the ratio of total deaths under one year of age to total live births). Infant mortality statistics suffer from under-registration, at least in earlier times, and from varying delimitation between still-births and infant deaths. Thus, in order to improve international and intertemporal comparisons, the foetal death rate (defined as the ratio of total children who are still-born or who die within a specified period after birth to total live births) has been added, in separate form and aggregated with the infant mortality rate.

The infant mortality rate is of course only one, although the most prominent, age-specific death rate. A more complete picture of the development of mortality requires the establishment of population life tables which are based on a complete set of mortality rates (i.e. the probability of dying within a year after reaching a particular age). These life tables are used to calculate age-specific life expectancy — always assuming stable mortality patterns. These data are presented here after the tables with the time-series, first in the form of four comparative graphs and second in tabular form. Whereas the graphs illustrate the prolongation of life expectancy at birth for men and women in a comparison of all countries, the tables give life expectancy at various ages for each single country.

The changes in mortality as well as fertility have greatly transformed the age structure of the European populations. Therefore, the chapter concludes with a set of tables and graphs with data on the age distribution of total population, male and female population. For comparative reasons, these data are presented as relative and not as absolute figures.

1818	13 477 934										

a) For the period 1818 to 1869 midyear population figures are estimated on the basis of figures given by population enumerations and censuses in January 1818, 1821, 1824, 1827, 1830, 1834, 1837, 1840, 1843, 1846, in October 1850 and 1857, and in December 1869. Therefore, population growth rates and net migration rates are only presented as average annual rates between these years.

b) From 1819 to 1855 the annual figures of live births and of deaths refer to the period from November 1 of the preceding year to October 31 of the respective year (e.g.: 1819 = 1 Nov. 1818 - 31 Oct. 1819).

c) For the period 1831 to 1870 figures on infant mortality and stillbirths have only been available as five-year-averages.

- a) Midyear population figures have been calculated on the basis of population figures at the end of the year. At least up to 1920, the system of population registration was unreliable, and population census figures were used to correct the figures. This procedure produced breaks in the years following the censuses which makes the calculation of annual population growth rates and net migration rates based on the midyear population meaningless. Therefore, from 1846 to 1920, population census figures (see Volume I) have been used to calculate these rates.
- b) Excluding 41 municipalities under direct German administration.
- c) Excluding 50 municipalities.
- d) On April 19, 1839 parts of the Belgian provinces of Limbourg and Luxembourg were ceded to the Netherlands. The 1839 midyear population has been estimated using population figures for these two provinces.

Year	Total population		
	Belgium	Limbourg	Luxembourg
1.1.1838	4 273 176	292 087	323 951
1.1.1839	4 317 944	295 112	327 885
1.1.1840	4 028 677	168 681	172 473

a) Population figures are based on the census population (but including those persons not counted under the census due to temporary absence from the country), the number of births, deaths and migrations. They refer to the following territory: 1815-1860: 538,000 sq.km, 1861-1870: 551,000 sq.km, 1871-1913: 536,000 sq.km, 1914-1975: 551,000 sq.km.

b) Children born alive who die prior to being registered (i.e. up until three days after birth) are counted as still-births. The number of live births thus only refers to the number of declared births and the number of still-births includes children born alive but dying prior to registration.

c) The number of deaths excludes children born alive but dying prior to registration.

d) Figures are official estimates based on statistics for 86/87 departments and available information for the other departments. The number of deaths does not include civil or military deaths due to war accidents (ca. 600,000 persons in the period 1939-1945).

e) Present territory. Figures are official estimates based on statistics for 77 departments. The number of deaths excludes military losses (ca. 360,000 in 1914, 320,000 in 1915, 270,000 in 1916, 145,000 in 1917, and 250,000 in 1918).

f) Territorial change.

a) Average resident population; 1841-1870: territory as of 1871-1937: territory of respective period; 1938-1943: territory as of December 12, 1937; 1946-1975: present territory, including West Berlin and Saare; 1946-1975: population registration figures corrected on the basis of the 1956, 1961 and 1970 censuses.

b) Territory as of December 12, 1937.

c) 1939-1943: excluding military losses.

d) Territorial change.

1862	21 838	833 054	681 212	38.1	31.2	7.0						1862

a) All figures refer to the present population in the respective territory.

b) 1862-1961: mean population calculated on the basis of end-year population figures; 1962-1975: mean population calculated on the basis of the 1961 end-year population and the annual figures of births, deaths and net migration.

c) Postwar territory, excluding Trieste.

d) Excluding deaths in war zones and deaths of military personnel abroad.

e) Territorial change.

a) Estimated midyear home population.

b) Total population, i.e. including members of H.M. Forces overseas.

c) From 3 September 1939 to 31 December 1949, for males, and from 1 June 1941 to 31 December 1949, for females, mortality rates are based upon civilian deaths only; but, as in other years, the number of deaths include those of non-civilians registered in the United Kingdom.

d) Figures are for civilians only

a) Estimated midyear home population.

b) Total population, i.e. including members of H.M. Forces overseas.

c) From 3 September 1939 to 31 December 1949, for males, and from 1 June 1941 to 31 December 1949, for females, mortality rates are based upon civilian deaths only; but, as in other years, the number of deaths include those of non-civilians registered in the United Kingdom.

Birth and death rates may be unreliable, but they do not create problems as to their 'meaning'. Obviously, the same does not hold true for a distinction between legitimate births, for marriage and divorce rates. Not only would an explanation of levels and changes in these rates require, as a first step, an understanding of institutional regulations, but the statistics themselves are already dependent upon these definitions.

Family and marriage are pre-legal institutions. For the Romans and the Germanic peoples, marriage and divorce were *de facto* rather than *de jure* matters, regulated by religious and group norms. After the breakdown of the Roman Empire in the West and the spread of Christianity, however, a long-term process of juridification began, from the extension of ecclesiastical jurisdiction over matrimonial matters to direct marriage regulation through State laws. This development of a marriage law common to all groups of a society was a unique European phenomenon. Only recently, this long-term development seems to have been reversed by a process of – at least partial – dejuridification.

The spread of Christianity eventually resulted in marriage being treated not only as a civil contract but also as a sacrament, a holy bond which was indissoluble. From the time that Christianity became the established religion until the eighteenth century, divorce *a vincolo matrimonii* (i.e. from the bonds of marriage), permitting remarriage, was generally not obtainable. Only divorce *a mensa et thoro* (i.e. separation from board and bed) was obtainable, but it did not permit remarriage. To some extent, however, the principle of indissolubility was mitigated by the possibility of an annulment, on the basis of grounds which pre-dated the marriage. The establishment of the doctrine of indissolubility and of ecclesiastical jurisdiction over matrimonial causes took centuries. For a long time marriage continued to be considered as basically a private and secular matter. Until the Council of Trent, there were two equally valid sorts of marriage, one public and formal, the other private and informal. Then the Tridentine Decree Tametsi provided that henceforth no marriage was valid unless it had been celebrated in the presence of a priest, and it prescribed the keeping of official records of marriages. What the Church established at the Council of Trent has never been repealed.

The Council was the outcome of the crisis which faced the Church in the sixteenth century. Among the churches which developed out of the Reformation, the attitude towards divorce varied, but in general it was accepted. Neither Luther nor Calvin considered marriage a sacrament. Only the Church of England inherited Roman canon law unchanged and divorce *a vincolo* did not exist until 1858. Protestantism, however, did not 'privatize' divorce. Instead it defined it as a sanction for marital misconduct to be granted by an ecclesiastical or civil official. Divorce by mutual consent was not recognized and the rules governing annulment were tightened up.

With the exception of England (where ecclesiastical jurisdiction over marriage survived until 1858), Protestantism accepted the notion of civil jurisdiction over marriage. Yet when the State first assumed this jurisdiction, it simply applied ecclesiastical norms. During the absolutist period, special exemption procedures were introduced, either by royal jurisdiction, as in most countries, or by private acts of parliament, as in England. These procedures, however, were of limited importance, and it was only during the Enlightenment that a new strand of thought, reviving Roman legal ideas, came to influence divorce legislation (especially in Prussia and Austria).

The influence of these ideas on divorce was only fully realized in the French Revolution. A law of 1792 defined marriage as a civil contract and permitted divorce by mutual consent. Although divorce by mutual consent was severely restricted by the Code Napoleon of 1804 and divorce abolished altogether in 1816, the revolutionary legislation was an indication of the future development of divorce law in Europe. These developments varied greatly across Europe, but in general they conformed to the following steps: introduction of divorce on the grounds of guilt and successive extensions of these grounds; introduction of divorce on the grounds of marital breakdown and successive efforts to make it more easily obtainable; finally, divorce by mutual consent, and corresponding efforts to make it available more quickly. The following table gives a synopsis of the major steps in divorce legislation in our European countries.

Divorce Legislation

Austria

- 1811 Divorce introduced for non-Catholics (General Civil Code)
- 1855 Concordat abolished divorce
- 1868 Divorce reintroduced for non-Catholics
- 1934 Divorce abolished
- 1938 German law adopted extending divorce to Catholics; on the combined grounds of guilt and marital breakdown; still basically in force today

Belgium

- 1804 Divorce on the grounds of guilt and (very restricted) mutual consent (Code Napoleon)
- 1969 Divorce on the grounds of mutual consent more accessible
- 1972
- 1974 Divorce on the grounds of marital breakdown introduced (retained some element of the guilt principle)

Denmark

Divorce on the grounds of guilt allowed since the Reformation, and exemptions made by the King.

- 1922 Divorce on the grounds of guilt, marital breakdown or by mutual consent (but only indirectly, after a period of legal separation)
- 1969 Divorce legislation similar to that of Sweden prior to 1973

Finland

Divorce on the grounds of one-sided guilt allowed since the Reformation; exemptions made by the King, by the parliament in the nineteenth century, and by the High Court since independence.

- 1929 Divorce on the combined grounds of guilt and marital breakdown
- 1948 Legal separation added, indirectly introducing divorce by mutual consent

France

- 1804 Divorce on the grounds of guilt and (very restricted) mutual consent (Code Napoleon)
- 1816 Divorce abolished
- 1884 Divorce reintroduced on the grounds of guilt
- 1975 Divorce on the grounds of marital breakdown and by mutual consent, in addition to guilt

Germany

Prior to the founding of the Empire in 1871, divorce legislation varied by province and denomination.

- 1875 Divorce introduced for Catholics; guilt the only grounds for divorce for Catholics and non-Catholics
- 1938 Divorce on the grounds of marital breakdown and guilt; law in force, with minor changes, until the 1976 reform

Ireland

Divorce not allowed, as the indissolubility of marriage is guaranteed by the Constitution.

Divorce Legislation

Italy

1970 Divorce on the grounds of guilt or marital breakdown introduced

Netherlands

1838 Divorce on the grounds of guilt and (very limited) by mutual consent (but only indirectly, after a period of legal separation)
1883 Supreme Court decision making (indirect) divorce by mutual consent easier
1971 Marital breakdown introduced as sole grounds for divorce

Norway

Since the Reformation divorce available on the grounds of guilt or by royal decree.

1909 Divorce on the grounds of guilt, marital breakdown and by mutual consent after a certain period of legal separation; still in force with minor amendments

Sweden

Since the Reformation divorce available on the grounds of guilt or by royal decree.

1915 Divorce on the grounds of guilt and marital breakdown, after a certain period of legal separation
1973 Divorce on the grounds of marital breakdown or by mutual consent, with no or only short period of separation

Switzerland

Since the Reformation divorce available on the grounds of guilt.

1912 Divorce on the grounds of guilt or marital breakdown

England and Wales

Since the break with Rome divorce was only possible by private acts of parliament.

1857 Divorce on the grounds of guilt
1923 Grounds for divorce equalized for men and women
1937 Extension of the grounds for divorce
1971 Marital breakdown the sole grounds for divorce

Northern Ireland

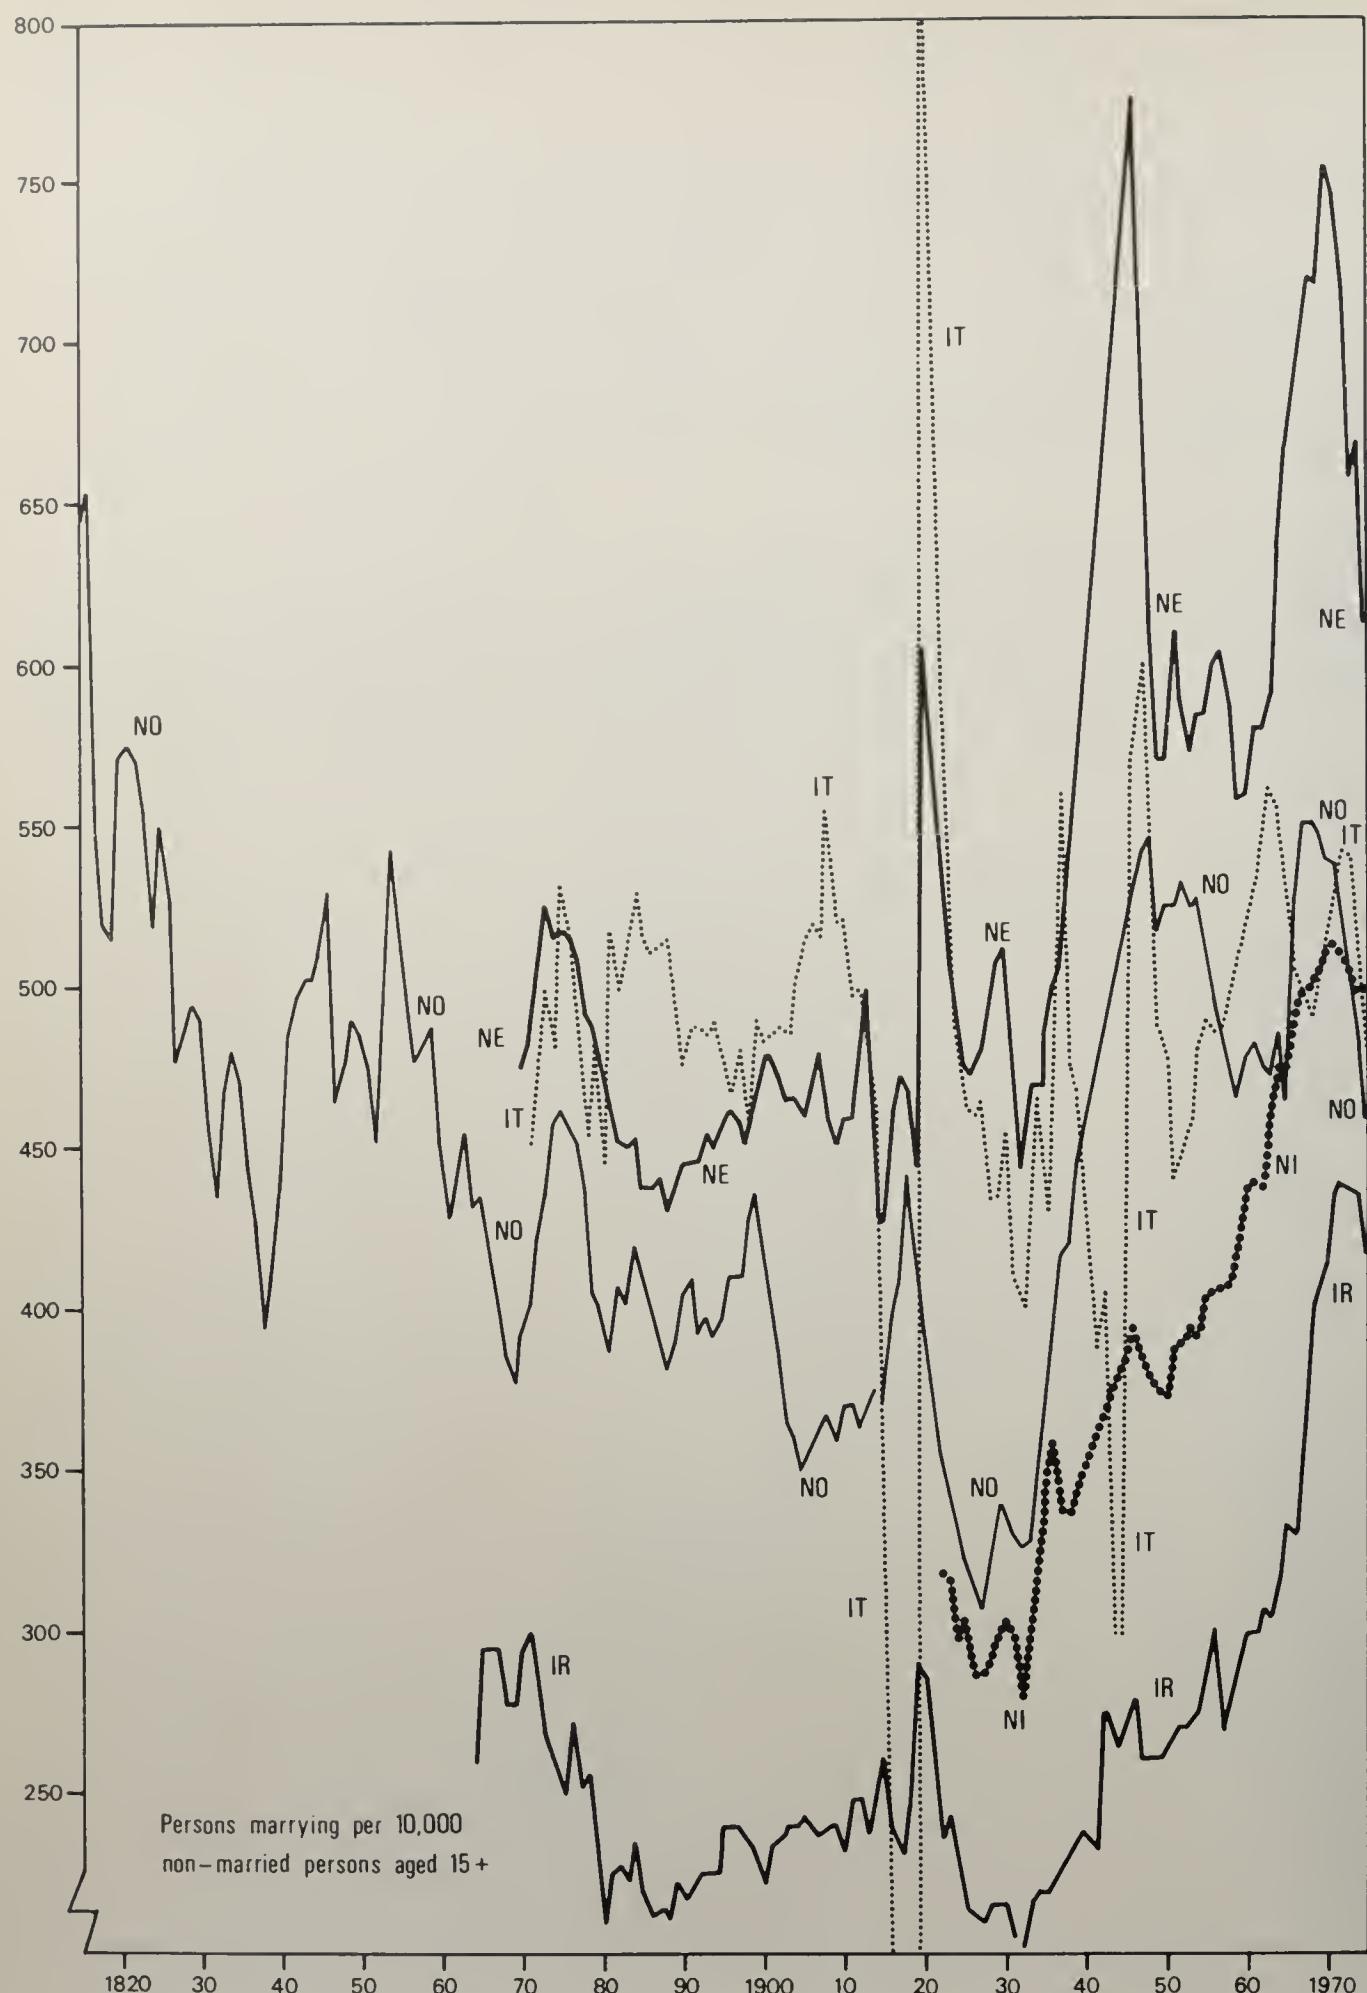

1939 Divorce on the grounds of guilt introduced (according the English law of 1937), still in force

Chapter 2 consists of two data sets. One is based on the statistics of civil registration, the other on population census results. First, the figures for marriages, divorces, legitimate and illegitimate births are presented, in absolute as well as in relative terms. In addition to three simple ratios (marriages per 1,000 population, divorces per 100 marriages, and illegitimate births per 100 legitimate births), five more complicated indicators have been calculated:

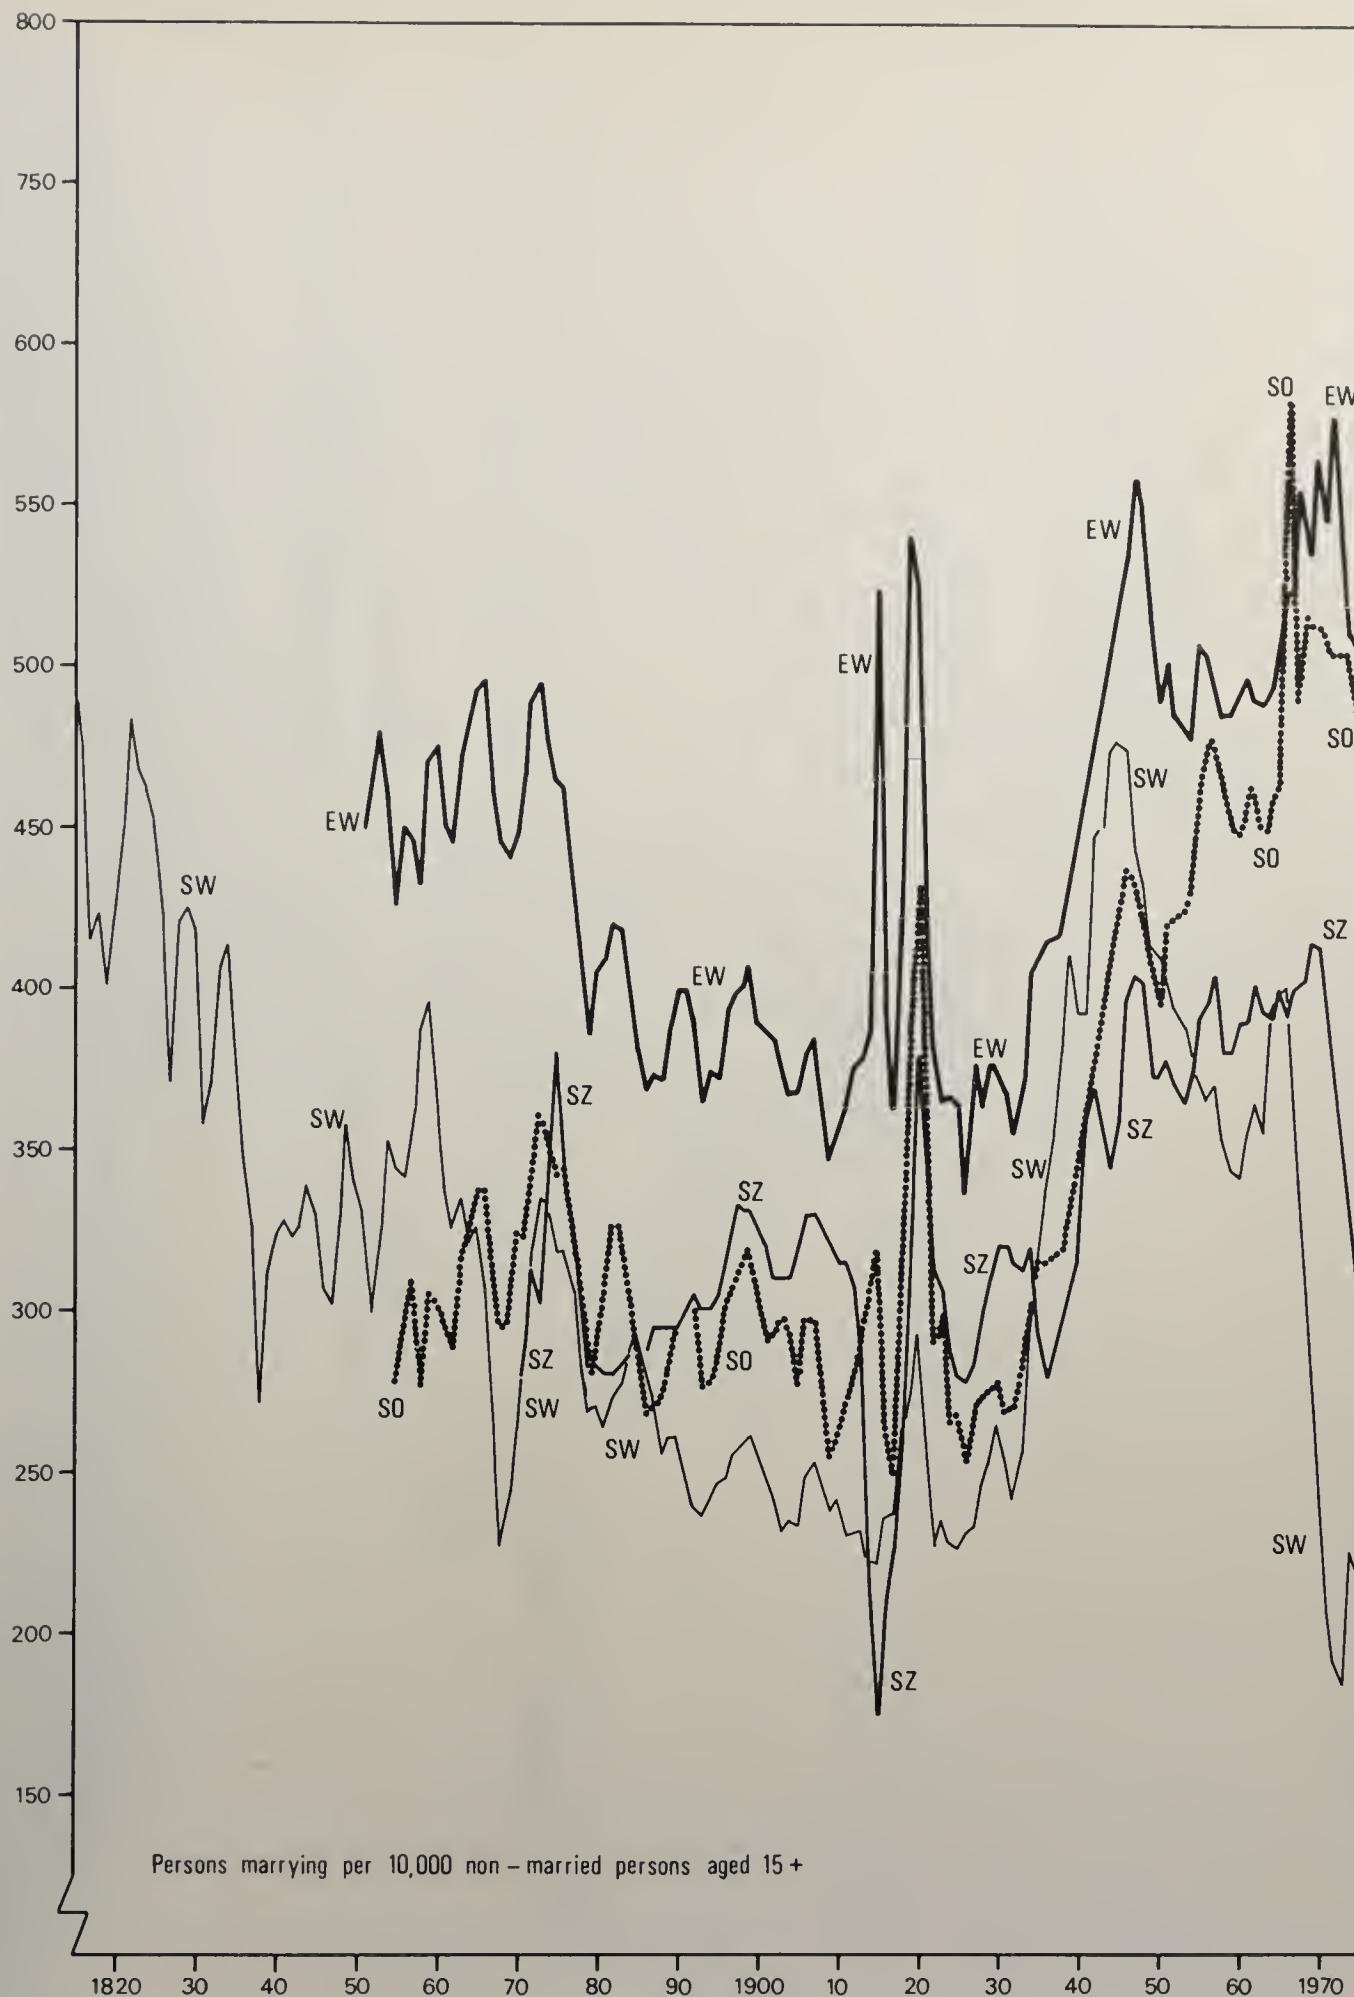

- (a) persons marrying per 10,000 non-married persons aged 15 years and over as a more refined marriage rate; in order to have some control for the ageing of the population (as old people marry much less frequently), a second indicator using the age group 15–49 has been calculated;
- (b) persons divorcing per 10,000 married persons as a more refined divorce rate;
- (c) legitimate births per 10,000 married women in the child-bearing age of 15–44, and illegitimate births per 10,000 non-married women of the same age, as more adequate indicators of fertility inside and outside marriage. We have calculated the respective population categories for these indicators on the basis of population census results. Their relative shares of total population have been interpolated for the intercensus years (except, in some countries, for the two World Wars) and extrapolated for the years after the latest census around 1970.

The tables present these data in the form of time series for each country in alphabetical order. They are preceded by a series of comparative graphs on the development of marriage, divorce, legitimate and illegitimate births. They are followed by the second set of data which consists of detailed breakdowns of the population by sex, civil status and ten age groups. These data are calculated from census results and are, for comparative reasons, given as relative figures, i.e. the respective distribution for each male or female by civil status.

a) First steps towards a secularization of marriage law were taken as early as 1783 and 1811. The General Civil Code of 1811 introduced divorce for the non-Catholic population. Catholics were only allowed separation a mensa et thoro, apart from the limited practice of marriage invalidation by the Church. This legal situation did not basically change until 1938. After World War I, however, legal separation (then referred to as 'divorce' in Austria) became almost identical with divorce (then referred to as 'separation'), as remarriage after separation was allowed by edict in some provinces. In 1938, after annexation, civil marriage was made obligatory and divorce was also introduced for Catholics. The new Austrian state took over the 1938 law with only a few changes regarding divorce. Divorce law is based on the principles of guilt and marital breakdown.

In the tables, divorce figures for the period 1882 to 1937 include divorces (D) for non-Catholics together with separations (S) for Catholics and other groups, but do not include invalidations (I). Figures for the latter are given below. From 1938 figures refer to divorces in the stricter sense.

Year	D	S	Year	D	S	I	Year	D	S	I
1882	97	651	1898	149	1 117		1919	272	3 887	12

a) Until 1974 divorce law was based on the Code Napoleon which allowed divorce on the grounds of guilt and by mutual consent. The latter was initially very limited, but became increasingly feasible, particularly as a result of the 1969 and 1972 amendments. A 1974 law (effective from 1975) introduced marital breakdown (as evidenced by a certain period of separation) as grounds for divorce. However, it retained some element of the guilt principle. Legal separation is obtainable on grounds similar to those for divorce, and may be turned into divorce after three years.

Divorce is granted by the courts but must be registered with the local Registrar's Office to become effective, thus giving us two sets of statistics, judicial and administrative, the latter being slightly lower. In the tables, divorce figures refer to registered divorces only. Figures on legal separations are not included. They are not available for the whole period and are of relatively minor importance.

a) Since the Reformation divorce was obtainable on the grounds of guilt. In addition, there was an exemption procedure by royal jurisdiction. A 1922 law introduced divorce on the grounds of marital breakdown, after a longer period of separation. Divorce by mutual consent was not permitted, but was indirectly obtainable after a period of legal separation. A 1969 law made divorce legislation similar to that of Sweden prior to 1973. In the tables, figures refer to divorces only, i.e. they do not include legal separations.

a) Divorce has been possible since the Reformation. A law of 1734 transferred jurisdiction over marriage from the Lutheran Church to the state. This law remained in force for almost two hundred years. It based divorce on a strict notion of one-sided guilt, but this restriction was eased by an additional exemption procedure which was a matter of free deliberation, first of royal jurisdiction, then of the Senate, in the nineteenth century, and finally of the Supreme Court after independence. This procedure introduced in practice the principle of marital breakdown. A law of 1929 (effective from 1930), codified this practice and based divorce legislation on a combination of the principles of guilt and marital breakdown. In 1948 provisions for legal separation were added, separation also being granted by mutual consent after a conciliation procedure, divorce being made possible after one year's legal separation.

In the tables divorce figures do not include these separations, the figures for which are given below.

Year	Number of separations	Year	Number of separations	Year	Number of separations
1949	462	1958	1 737	1967	2 501
1950	635	1959	1 731	1968	2 932

a) Under the Old Regime only legal separation and annulment were allowed. The 1804 Civil Code introduced divorce on the grounds of guilt, and by mutual consent (very restricted). During the Restoration the ecclesiastical marriage law was reintroduced and divorce abolished. In 1884, a new law reintroduced divorce, but only on the grounds of guilt. This remained in force until 1975 when a new law (effective from 1976) allowed divorce by mutual consent and on the grounds of marital breakdown (in addition to guilt).

Divorce is granted by the courts but must be registered within a certain period in order to be effective. Thus, there are judicial and administrative divorce statistics, the latter being slightly lower. In the tables divorce figures refer to divorces granted by the courts. Legal separations have not been taken into account.

b) Present territory. Figures are official estimates on the basis of statistics for 77 departments.

a) Prior to the founding of the German Empire in 1871, divorce law differed by province and denomination. In principle, the Protestant states allowed divorce on the grounds of guilt (in Prussia, to a limited extent, also by mutual consent), whereas the Catholic states prohibited divorce for the Catholic population. In 1875, a uniform law made divorce obtainable for Catholics, but only on the grounds of guilt. In 1938, compulsory civil marriage was introduced and marital breakdown became an additional grounds for divorce. The 1938 law remained in force, with minor changes, until the 1976 reform.

In the tables, figures refer to divorces only.

a) Legal marriage is indissoluble in Ireland, and the Constitution expressly provides that no law shall be enacted providing for the dissolution of marriage. The only forms of marriage dissolution available are the very limited ones afforded under ecclesiastical law.

a) The 1838 Civil Code basically reaffirmed the 1810 Code Napoleon in that it allowed divorce on the grounds of guilt. Divorce by mutual consent was not completely excluded, because divorce could be obtained after a legal separation of five years. In 1883, a Supreme Court decision made divorce (indirectly by mutual consent) easier. This situation lasted until 1971 when a new law made marital breakdown the sole grounds for divorce. In the tables figures refer to divorces only, i.e. they do not include legal separations, the figures of which are given below.

Number of legal separations

a) Since the Reformation divorce was allowed on the grounds of guilt. In addition, marriage could be dissolved by royal exemption. In the same period, legal separation was introduced. It was first intended as a final solution, but gradually became a step towards divorce. In 1909, a new law gave the right to divorce after a certain period of legal separation. This law basically is still in force and combines the three main grounds for divorce, guilt, marital breakdown and mutual consent.

In the tables figures refer to divorces only, i.e. they do not include legal separations, the figures for which are given below.

Number of legal separations

1895	109	1911	419	1927	905	1944	1 791	1960	2 411

a) Since the Reformation divorce was allowed on the grounds of guilt. In addition, divorce was possible by royal exemption. In 1915, a new law based divorce on the two principles of guilt and marital breakdown. Divorce was possible after one year's legal separation. In 1974, marital breakdown became the only grounds for divorce, making it much easier to obtain.

In the tables figures refer to divorces only, i.e. they do not include legal separations, the figures for which are given below.

Number of legal separations

1916	744	1926	1 924	1936	3 380	1946	7 830	1956	9 248	1966	11 537

a) Since the Reformation divorce was obtainable on the grounds of guilt. In 1912, divorce on the grounds of marital breakdown was introduced. In addition, a legal separation is allowable on the same grounds as divorce.

In the tables, figures refer to divorces only, i.e. they do not include legal separations, the number of which always amounted to less than 10 percent of divorces.

a) In general, divorce was not obtainable prior to 1859, but only separation a mensa et thoro. To a limited extent, however, divorce was obtainable by private acts of parliament. In 1859, civil marriage was introduced and divorce was permitted on the grounds of guilt. In 1923, the existing grounds for divorce were equalized for men and women, and in 1937, they were considerably extended. Finally, a 1971 law made marital breakdown the sole grounds for divorce.

In the tables, divorce figures include until 1938 the small number of annulments, but they do not include legal separations, the number of which was always less than 1 percent of divorces.

Urbanization and Housing

CITIES AND URBANIZATION

This chapter contains data on the growth of cities and the process of urbanization. Urban growth is not the same as urbanization. Cities have a history of almost ten thousand years, whereas urbanization is a more recent phenomenon. Urbanization implies the relative growth of the urban population, i.e. the increase in the proportion of the total population of an area living in cities. In this simple ecological sense, urban growth can occur without urbanization, if the rest of the population increases at the same or a faster rate; and urbanization may occur without urban growth, if there is a faster decline of the rural population (as happened in Ireland in the last century).

Urban growth may be the result of one or more of four factors: (1) the natural increase of the urban population, (2) the net migration into cities, (3) the annexation of inhabited areas or communities adjacent to existing cities, (4) the transformation of non-urban communities into cities. How can one distinguish cities from non-urban communities? The easiest way, in principle, is to define the difference in terms of size and density. Urban growth then may simply mean that during a given interval some communities pass a statistical threshold.

Even if one applies only a numerical standard, however, one has to solve the problem of how to define the boundaries of a community or city. There are in principle two alternative solutions. One is to define the boundaries in terms of the economic interdependence and social interrelations of a population in a territory, using indicators of processes of exchange, communication and mobility. This is obviously difficult; and it is not feasible for a data set covering more than a dozen countries and one and a half centuries. The second alternative is to simply accept the boundaries of incorporated communities which underlie the official statistics. This has been done here.

One must be aware, however, that these official boundaries frequently do not correspond with the 'real boundaries' of communities. Three typical cases can be distinguished. The first refers to local communities which as administrative units embrace a number of separate settlements. The average number of such settlements varies greatly between and even within countries, but sometimes we know at least the size of the central settlement. This problem arises mainly with the smaller communities, and one may reasonably assume that from 20,000 and more inhabitants, communities are largely identical with the central settlement. We have therefore used this criterion (in addition to 100,000 and more inhabitants) in our comparative tables at the beginning of the chapter, which show the relative increase of the urban population across Europe.

The second case where official and 'real' boundaries do not correspond is the case of suburbanization. Many suburbs which have outgrown the boundaries of the city to which they belong, have been incorporated with a considerable time lag only, and then this incorporation produces an artificial jump in the rate of urbanization. To some extent, this can be seen from the tables which give population figures for individual cities.

The third case, the development of metropolitan areas, poses more fundamental problems. One approach to the study of cities lies in the analysis of the distribution of activities within a territory. From this perspective, cities consist of nodes with a higher density and specialization of activities, and tributary areas. Increasing urbanization produces a growing interrelatedness of urban communities and leads to the development of new urban systems at a higher level: the development of metropolitan areas. With our simple data this complex process cannot be measured. Any attempt to do so would require detailed studies which are available for a few countries and periods only.

The boundary problems in a quantitative study of urbanization are not merely problems of relatively arbitrary statistical classifications, but reflect historical changes. The medieval town was an organism in itself, clearly separated from the rural areas. Until the nineteenth century, the European cities remained separate entities, even when the walls had been torn down. However, this changed with the process of industrialization. Industrial urbanization differs from other forms of urbanization not only in quantity but

also in quality. The city increasingly lost its specific social form; networks of interaction and communication became more diffused; and the urban-rural differences in the way of life tended to become less profound. For all these reasons urbanization rates have lost much of their former significance, at least since World War II.

Even if cities as single units have changed their character, the networks of cities still exhibit characteristics which they acquired centuries ago. We therefore present two comparative tables at the beginning with measures of the monocephaly or polycephaly of the city networks: the population of the capital as a percentage of the total population and as a percentage of the five biggest cities including the capital. Together with the other two comparative tables with measures of the degree of urbanization, they depict the basic outline of the urban structure of a country.

The comparative tables are followed by national tables, two for each country. First, population shares by size of locality are given in tabular and graphical form. Localities or communities are usually classified according to the following categories (number of inhabitants): 0–2,000, 2,000–5,000, 5,000–20,000, 20,000–100,000, 100,000–1,000,000, 1,000,000 and over. The second table contains population figures for the major cities of each country. For the majority of countries, the criterion of 20,000 inhabitants in 1910 has been chosen for selecting the cities. For the Austrian Empire, France, Germany, Great Britain and Italy a different criterion has been utilized in order to reduce the number of cities.

HOUSING CONDITIONS

This chapter provides basic data on the long-term development of housing conditions of the total population or the urban population or both. Mass housing has improved since the nineteenth century in size, fittings, and standards of layout, but it is only for the size that quantitative data are available during the period under consideration. Thus, the main measure of housing conditions used here is the number of persons per habitable room which gives a rather good indication of the amount of space and degree of privacy these persons have. One must be aware, however, that the person/room ratio takes no account of other qualitative improvements in housing which may have occurred at the same time.

Buildings have been enumerated in population censuses from the very beginning, normally as a by-product of the enumeration of the population. In counting people one used to ask how many buildings were inhabited and by how many families/households they were occupied. More detailed data, however, especially on the size of dwellings, did not become available at the national level prior to the end of the nineteenth century, at a time when rapid population growth and urbanization reached a peak volume, intensifying housing problems.

Governments took little direct responsibility for housing before the turn of the century, with the exception of protective legislation against the worst and unacceptable housing and health conditions. Later, some countries also encouraged self-help schemes through cooperatives and unions in working-class housing construction. It is therefore not surprising that more detailed housing statistics did not become available before the turn of the century and frequently only after World War I, when the disruption of housing production during the war and an increased household formation after the war created severe housing shortages.

However, even if we limit ourselves to questions of size and density of housing, difficulties of data comparability are not negligible. A major problem lies in the fact that there are two units of analysis in housing inquiries which do not coincide: the dwelling, and the family or the group of individuals who occupy in common a dwelling or part of it. In general, a dwelling is any room or suite of rooms intended or used for habitation which has a separate access to the street or to a common landing or staircase. Usually, a dwelling lodges only one household, but it may also contain two or more households or families. The definition of a separate dwelling may vary, but the definition of a household is usually more problematic. In general it includes, in addition to the nuclear family, other relatives and indoor domestic servants. Other categories of people, such as lodgers, however, may be treated rather differently from census to census. In more recent times, the increasing share of households formed by persons without kinship or marriage ties creates new problems of comparability.

Housing statistics are normally confined to private households and thus exclude individuals in hotels or boarding houses, in hospitals or institutions for the old, infirm or poor, in schools and prisons, etc. However, on average private households comprise more than 95 percent of the total population. In the enumeration of dwellings a first distinction has to be made between vacant and occupied dwellings. Vacant dwellings may be tenantless or simply not occupied at the time of the census. For these dwellings the information on the number of rooms and persons is of course less reliable and less complete. Data on the distribution of dwellings by size, therefore, frequently refer to occupied dwellings only.

For each (occupied) dwelling usually the following information is collected: the number of households/families living in the dwelling, the number of persons and rooms per household/family. The enumeration of rooms is not without problems: living and bedrooms are always counted, sculleries, landings, lobbies, closets and bathrooms are never counted, but the kitchen may be treated rather differently. In dwellings with more than one household, the treatment of rooms used in common may also vary. Normally, however, more than 90 percent of all dwellings are occupied by one household only.

In the main table on the housing conditions in each country, four data sets are presented:

- (1) the distribution of households or dwellings by the number of rooms;
- (2) the distribution of households by size, i.e. by the number of persons;
- (3) the density of occupation, i.e. the number of persons per room, by household size;
- (4) the distribution of all households by density of occupation.

The improvement of housing conditions in terms of the density of occupation is not only the result of an expanding living space of households. It is also the product of a shrinking household size. The same spatial separation of functions implies much lower ratios of persons to rooms for smaller than for larger households. On the basis of the four data sets, it becomes possible to distinguish and weight the two factors in the development of occupancy rates. No attempt has been made to develop a consistent measure of 'over-crowding' which usually is defined as a person/room ratio in excess of a certain arbitrary limit. Frequently the share of households with ratios of more than two persons per room is taken as an index of overcrowding. Sometimes, however, children are counted differently, and the requirement of a sex separation of unmarried people above a certain age is used in addition to a simple person/room ratio.

In addition to the main tables with the basic housing statistics, more complex cross-tabulations are given for most countries which show the distribution of dwellings by the number of persons *and* the number of rooms. These tables represent the most important general source for an analysis of the inequality of housing conditions among households. Of course, one would have to know more about the households than only their size in order to derive from these housing statistics a more concrete idea of the social structure of the population. However, the complexity of housing statistics has discouraged such an attempt from the very beginning.

Whenever possible, housing statistics are presented for the total population, but sometimes they are only available for the urban population or perhaps only for single cities (which have been included in cases where they represent a larger proportion of the total population, such as Vienna or Copenhagen).

VIII

Economic Growth

GROWTH OF NATIONAL PRODUCT

This chapter presents data on the growth of national product in the form of aggregates and per capita values. Figures are usually given for the following concepts: the GDP (m) or gross domestic product at market prices which is the broadest concept, the NDP (m) or net domestic product at market prices, and NDP (f) or net domestic product at factor cost which is the most narrow concept. In addition, per capita figures are given for the GDP (m) and the NDP (f) in order to standardize for differences in population size. Two tables are included for each country with figures at current and at constant prices.

Attempts to estimate a country's economic performance can be traced back as far as the seventeenth century, the most famous examples being the estimates developed for England by William Petty and Gregory King. These early estimators were modern in following a comprehensive production concept which later, mainly under the influence of Adam Smith, narrowed in scope to the production of material commodities. This restricted concept was only overcome in the late nineteenth century, above all by Alfred Marshall who identified production with the creation of utility, thus encompassing services as well as commodities. Since then the comprehensive production concept has become the accepted approach in Western countries.

Until World War I, estimates of national product were largely undertaken by individual investigators. Following the earlier attempts in England and France, first estimates were prepared in Austria in 1861, in Norway in 1893, in Germany in 1899 (there were earlier estimates for single German countries), in Switzerland in 1902, in the Netherlands in 1910 and in Italy in 1911 (cf. Paul Studenski, *The Income of Nations*, 2 vols, New York 1961). In the interwar period, central governments increasingly took over national product estimation and put it on a regular basis. The conceptual as well as empirical foundations were considerably improved. The real breakthrough, however, only occurred after World War II. In 1953 the UN Statistical Office published 'A System of National Accounts and Supporting Tables' which provided a standardized framework (SNA) also for the collection of data on the origin, distribution and use of national product, a decisive step in promoting consistency in national accounting estimates.

National product estimates are pieced together from a variety of sources by different methods. Major sources are, among others, tax statistics and government budget reports, occupational, industrial and other economic censuses, production, price and wage statistics, household and other sample surveys, foreign trade and payments statistics. Prior to World War II, only single estimates were usually made which combined partial and complementary information on the origin, distribution and use of national product. With the improvement of the data basis, however, it became possible to estimate the national product in three largely independent ways using the sector value-added (origin), the income (distribution), and the expenditure (use) approach. This procedure normally leads to different estimates of national product and the statistical discrepancies may be used for a judgement of the reliability and a further refinement of the estimates. Unfortunately, however, they are separately shown only recently. In the former SNA, the value-added approach and the expenditure approach have been adjusted to each other (the statistical discrepancy increasingly being allocated to changes in stocks, i.e. to the expenditure side), whereas deviations of the income approach estimates have frequently been included under the statistically less reliable category of entrepreneurial income.

The elaboration of the basic sector accounts and the improvements in the quality of data since the early 1950s have made the current national product figures in general sufficiently reliable and comparable. For the period prior to World War II, however, one has to rely on a variety of historical studies. Many of them were carried out in the 1960s under the auspices of Simon Kuznets. These studies, in contrast to earlier estimates, all depart from a common framework of national accounts concepts. However, given the scarcity of adequate data, they too have to rely to large extent on indirect and partial evidence and simple estimation procedures (sometimes considerable shares of the national product have been linearly interpolated over decades!). These national product figures obviously do not allow for analyses of annual changes, but only of broad trends and patterns.

Relying on a variety of historical studies, we have tried to link series for different periods whenever figures for overlapping years have been available. Data from SNA have not been linked, however, to those from historical studies. Respective figures for overlapping years instead are given in the notes. Chaining has also been applied to the time series at constant prices when different price bases overlapped. Only in a few cases (e.g. Italy) small modifications have been made to improve comparability. Such changes or combinations of various series are documented in the notes to the tables. For a fuller explanation of the problems involved in statistical definitions, the empirical basis and the estimation procedures, we must refer to the sources which we have used and which are documented in the appendix.

It is difficult to adequately solve the various measurement problems, but it may be even more problematic to find an acceptable definition of the national product which can be used over long stretches of space and time. According to Simon Kuznets (*Economic Growth of Nations*. Harvard University Press 1971), these problems may be grouped under three headings:

- (1) the distinction between economic activity and social life (questions of scope or of inclusion and exclusion);
- (2) the distinction between costs and net returns of economic activity (questions of grossness and netness);
- (3) the definition of a common denominator of economic activities and their products (questions of valuation or weighting).

National product estimators have in general tended to delimit economic activities in terms of transactions which are channeled through markets or through other social institutions (e.g. governments) which also are extraneous to the family or household. In addition, value imputations may be made for various non-market activities that have market counterparts (e.g. food produced and consumed on farms, the rental value of owner-occupied houses, etc.). Usually, however, such imputations fall considerably short of measuring all activities that contribute to economic welfare (e.g. the services of housewives). As economic growth is often accompanied by a shift in economic activities from the household to the marketplace, it follows that long-term product estimates closely tied to market criteria tend to exaggerate the rate of growth.

National product is defined as the total production of final goods (commodities and services, net of imports) within a period. Intermediate goods, i.e. products which are used up in the production of other goods, should be excluded, but the distinction between costs and net returns of economic activity is far from being unambiguous. Final goods must be related to basic goals of economic activity. Even if one sees the basic purpose as lying in the satisfaction of human wants, present and future, through the production of consumer goods (and by additions to capital stock), important conceptual problems remain. These refer above all to government activities which may be considered instrumental for the production of goods. In practice, final products are simply defined as those which have not been purchased and charged to current cost by other producers in the same accounting period, and intermediate products as those which are consumed in the production process. For this reason, products which could not be sold are counted as investment (i.e. changes in stocks), and the cost of governmental activity is counted either as public consumption or as public investment.

Conceptually, net measures are preferable to gross measures. Frequently, however, product estimates are presented gross of the fixed capital outlays which are required to offset the consumption of fixed capital goods. This is done because of the difficulties in measuring depreciation in current market values. For this reason, we present in the tables figures for the gross as well as the net domestic product and we also include the depreciation estimates. Both product figures are given at market prices. These are not equal to relative factor costs because of the influence of indirect taxes and subsidies. We have therefore included a third time series with estimates for the net domestic product at factor cost, and we have also given the net figures of indirect taxes and subsidies.

All three product figures refer to the domestic and not to the national product. We thus focus on the productive activity carried out within the boundaries of a country, regardless of the residence of the owners of the factors of production. If we had been interested in studying income and expenditure, it would have been more meaningful to use the concept of national product, i.e. to add the income of a country's residents from their property or labour used abroad and to subtract the income paid to foreign residents. With few exceptions, however, the differences between the national and the domestic product are insignificant for most purposes.

The goods and services subsumed under the national product are weighted by a price system which reflects socially set priorities. Real product is generally obtained by dividing the current value of goods and services by appropriate price indexes. In using such price deflators for long-term records of national product, two main problems are encountered. First, these indexes may not adequately reflect changes in the quality of goods and services, leading to an underestimation of the rate of economic growth. Secondly, the real growth rate may also depend on the time point which is chosen for the common system of price weights, since price relations change during economic growth. The domestic product figures at constant prices must therefore be interpreted with great caution. The use of price deflators for different time points and the simple chaining of price indexes for different periods set limits to their intertemporal and international comparability.

Time series of product estimates at internationally comparable constant prices, the so-called constant purchasing power units, have not been included here. They only cover the period after World War II, and comparative collections are already easily available (I. B. Kravis, A. Heston and R. Summers: *World Product and Income*, Baltimore 1982; R. Summers and A. Heston: *Improved International Comparisons of Real Product and its Composition 1950–1980*, *The Review of Income and Wealth*, 30,2,1984). The following data collection on domestic product was finished in 1977 and no attempt has been made to update it although additional material has become available in the meantime.

a) Figures are from different sources which are not strictly comparable.

b) Figures for 1926 to 1951 are for GNP at factor cost.

c) For 1952 the corresponding figure for GNP at factor cost is 413.

d) For 1952 the corresponding figure for GNP (f) per capita is 140.

- a) Figures are not strictly comparable because of differences in accounting systems. According to the earlier system the corresponding figures for 1951 are 25 050; 1 499; 23 551; 1 647; 21 904; 5 820; 5 089.
 b) Small changes in territory.
 c) Figures for 1818-1843 no longer refer to Domestic Product at market prices but to Domestic Product at factor cost.

Finland

- a) Figures are not strictly comparable because of differences in accounting systems. Corresponding figures for 1952 are 137 000, 11 500, 125 500, 19 800, 105 700, 2 654, 2 048.
 b) Considerable changes in territory.
 c) Figures for GDP and NDP at market prices are from different sources which are not strictly comparable; depreciation figures therefore are only crude estimates.
 d) Figures for 1850-1871 refer to NDP.

a) Figures for 1900 to 1939 are not for GDP(m) but for NDP(m).

b) Prior to the First World War data for National Product do not include Public Consumption and Public Investment.
Hence, comparability over time and between countries is severely impaired.

a) Figures are not strictly comparable because of differences in accounting systems.

b) Figures for 1865 to 1950 are not for GDP(m) but for Gross-GDP(m), i. e. are inclusive of repair and maintenance. For 1951 Gross-GDP(m) amounts to 20 456 and Gross-GDP(m) p.c. to 6 208.

c) Figures for 1865 to 1950 in addition include repair and maintenance.

For 1951 the corresponding figure is 3 705.

- a) Figures are not strictly comparable because of differences in accounting system.
 b) Figures for 1910-1950 are not for Domestic Product but for National Product. For 1951 the corresponding figures are 39 593 and 5 998.
 c) Figures for 1861-1950 are not for NDP(f) but for Gross-GDP(f), i.e. inclusive of depreciation, repair and maintenance. For 1951 the corresponding figures are 2 307 and 4 740.

- a) Figures are not strictly comparable because of differences in sources. According to the historical source the corresponding figures for 1960 are: 25 412; 1 933; 23 479; 2 904; 20 575; 485; 393.
 b) For 1830 to 1921 Southern Ireland is included.
 c) Figures for 1830 to 1854 are not for Domestic Product but for National Product, which, in addition, does not include changes in stocks.
 For 1855 the corresponding figures for National Product are: 744; 47; 697; 59; 638; 27; 23.

a) Figures for 1900 to 1939 are not for GDP(m) but for NDP(m).

b) Prior to the First World War data for National Product do not include Public Consumption and Public Investment.
Hence, comparability over time and between countries is severely impaired.

c) For 1952 the corresponding figures at 1963-prices are 34 500 and 3 323.

a) For 1865 to 1950 figures are not for GDP(m) but for Gross-GDP(m), i.e. inclusive of repair and maintenance.

b) For 1865 to 1950 figures in addition include repair and maintenance.

c) For 1951 the corresponding figures at 1955-prices are 22 813; 4 247; 18 566; 6 923; 5 634.

a) Figures for 1830 to 1869 are not for Domestic Product but for National Product.

b) For 1960 the corresponding figures at 1900-prices are 4 584; 320; 4 264; 88.

c) For 1830 to 1921 Southern Ireland is included.

d) Figures are based on linked deflators.

ORIGIN AND USE OF NATIONAL PRODUCT

Modern economic growth is more than growth of aggregate or per capita national product. It is usually accompanied by far-reaching structural changes which may be grasped in terms of changes in the origin, distribution, and use of national product. Modern economic growth implies a shift from agricultural to industrial production and to services, changes in the distribution of national income among social classes as well as changes in the use of national product for private household or government consumption or for capital formation. This chapter presents basic data on the origin and use of national product. Data on the distribution of national income are given in Chapter 8, Income Distribution.

The changes in the sectoral origin of national product reflect changes in the structure of final demand. To some extent, these changes are influenced by political decisions (consider the growing importance of government consumption), but on the whole they are mainly a product of the overall rise in per capita income as well as of the different impact of technological progress on the production of the various categories of finished goods. As income elasticities of demand for these goods differ, productivity increases lead to a changing structure of domestic final demand and hence to changes in the production structure.

A wide variety of industrial sectors could be distinguished on the basis of the characteristics of their products and of the technology and organization utilized in the production of these goods. Typically, industrial sectors differ markedly in the institutional setting of production and the character of work, in the level of productivity and the prospects of growth, and hence the positions and opportunities of the people working in them. A major problem in the identification of production sectors lies in the rather loose correspondence between types of economic activity (such as extracting, manufacturing, distributing, and financing) and statistically classifiable industrial groupings (such as mining, manufacture, commerce, etc.). Thus, activities subsumed under a certain industrial sector may greatly vary, especially with regard to applied technology. In this sense, measures of the change in sectoral shares of national product may rather underestimate the long-term changes in the production structure.

The estimation of the value added of the industrial sectors raises problems of its own. In principle, there are two basic methods of measurement. A sector's contribution may be measured in terms of the value of its total product net of purchases or in terms of the total income from work or property within the respective sector. The first method requires a full statistical account of input-output flows among the various industrial sectors. It involves a high risk of double counting, and adequate statistics are usually not available for the period prior to World War II. Therefore, this method has only recently become a major tool for independent estimation. The second method, the income approach, relies on a piecing together of various income and employment statistics (and supplementary information from production and price statistics). Historical estimates are mainly based on this approach which suffers from the fragmentary nature of the statistical materials.

Because of the above mentioned conceptual and empirical problems, only three major economic sectors are distinguished (cf. also Chapter 7, Labour Force): a primary (agriculture, forestry, and fishing), a secondary (mining, manufacture, construction, and utilities), and a tertiary sector (commerce, transport and communication, banking, private services and public administration.). Figures are provided in the form of percentage distributions. They usually refer to the time series of domestic product at current market prices (see Chapter 5), but sometimes to the gross or even the net domestic product at factor cost (cf. notes to the tables). A more comprehensive analysis of sectoral changes would certainly have to consider not only nominal but also real changes in sectoral value added. Because of the great index problems involved in such historical estimates, however, we have not included these figures.

The national product may be used in two principle ways: it may be consumed or added to capital stocks. Usually a further distinction is made between private and public consumption. Private consumption, by far the largest component, covers the expenditure on all consumer goods by private households and non-

profit institutions, but excludes the purchase of land and dwellings. Public consumption comprises the cost of services provided free of charge by general government (excluding government enterprises and public corporations) and all military expenditure. Finally, gross capital formation is the gross value of goods added to the capital stock, including residential construction, but excluding defense equipment.

Defining consumption as the use of goods to satisfy demands of ultimate consumers, and capital formation as additions to the stock of tools used to produce other goods, the line of distinction seems to be easily drawn. In reality, however, this distinction involves several conceptual problems. Investment in human capital (education, medical services etc.) is considered in national accounts as consumption, whereas investment in physical capital, including housing, is always classified as investment. Similarly the consumption of capital (depreciation) is included under gross investment, while the reproduction costs of human labour are defined as consumption. Changes in stocks are in principle classified as investment, even if they consist of consumer goods which have not been sold in the period of observation.

Perhaps the greatest conceptual problem refers to that varying part of private and public consumption expenditure which may be interpreted as individual or social costs of production. Public services, such as general administration, legislation, education or defense, cannot easily be understood as goods which satisfy the demands of final consumers. They rather represent intermediate goods (cf. the introduction to Chapter 5) or social production costs. And the same holds true for many expenditure items of private households (e.g. transportation) which represent individual production costs in a modern economy.

Consumption and investment are the basic categories of the use of national product. In order to arrive at the national product, one has to add the net balance between exports and imports to the domestic products. From the expenditure side, national product is defined as the sum of domestic consumption (private and public), domestic investment (private and public), and exports (net of imports). The following tables give the percentage distribution of national product according to these main categories of use. Figures usually refer to domestic product at current market prices, and in some cases to national product. In the latter case, exports (net of imports) include not only goods and services, but also the balance of factor remuneration to and from abroad (cf. notes to the tables). It should be noted that the share of total consumption, being the largest single category, can exceed the 100 % mark, when a country has become a net importer of goods and services.

An evaluation of changes in the allocation of production resources would have to take into account not only nominal changes, but in addition changes in the relative price relations between consumer and investment goods. Deflation raises a number of severe conceptual problems. Historical estimates also suffer from the insufficiency of the date basis. For these reasons, we have not included distributions at constant prices.

a) Figures refer to Gross-GDP (i.e., are inclusive of repair and maintenance) at factor cost.

b) Prior to 1947, GDP at market prices is without changes in stocks.

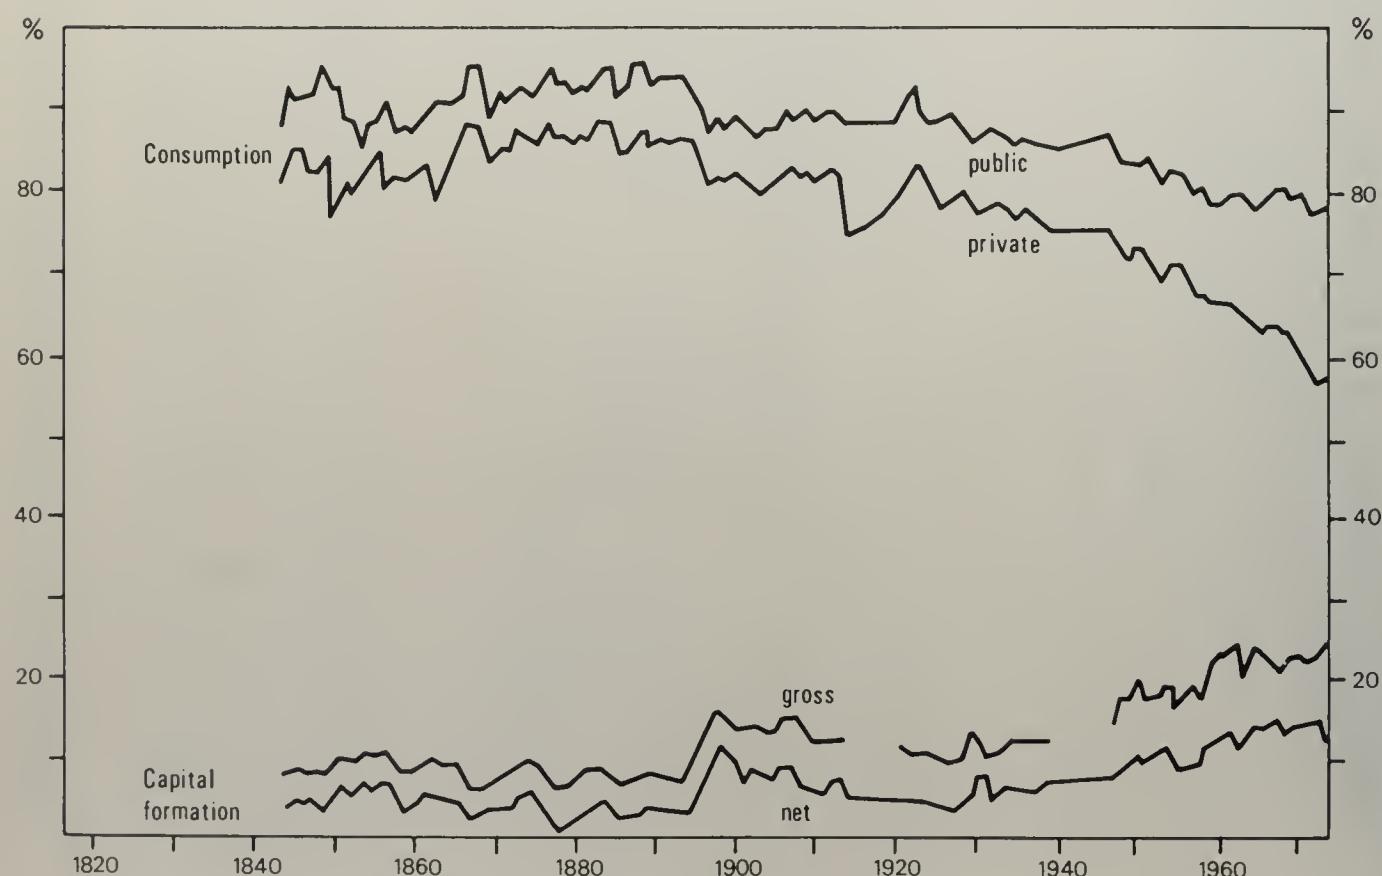

c) Prior to 1947, agriculture is without fisheries.

a) Figures for 1930-1939 refer to Gross-GDP (i.e. are inclusive of repair and maintenance).

For 1951-1968 they refer to GDP at factor cost. For 1969-1975 market prices are net of value added tax.

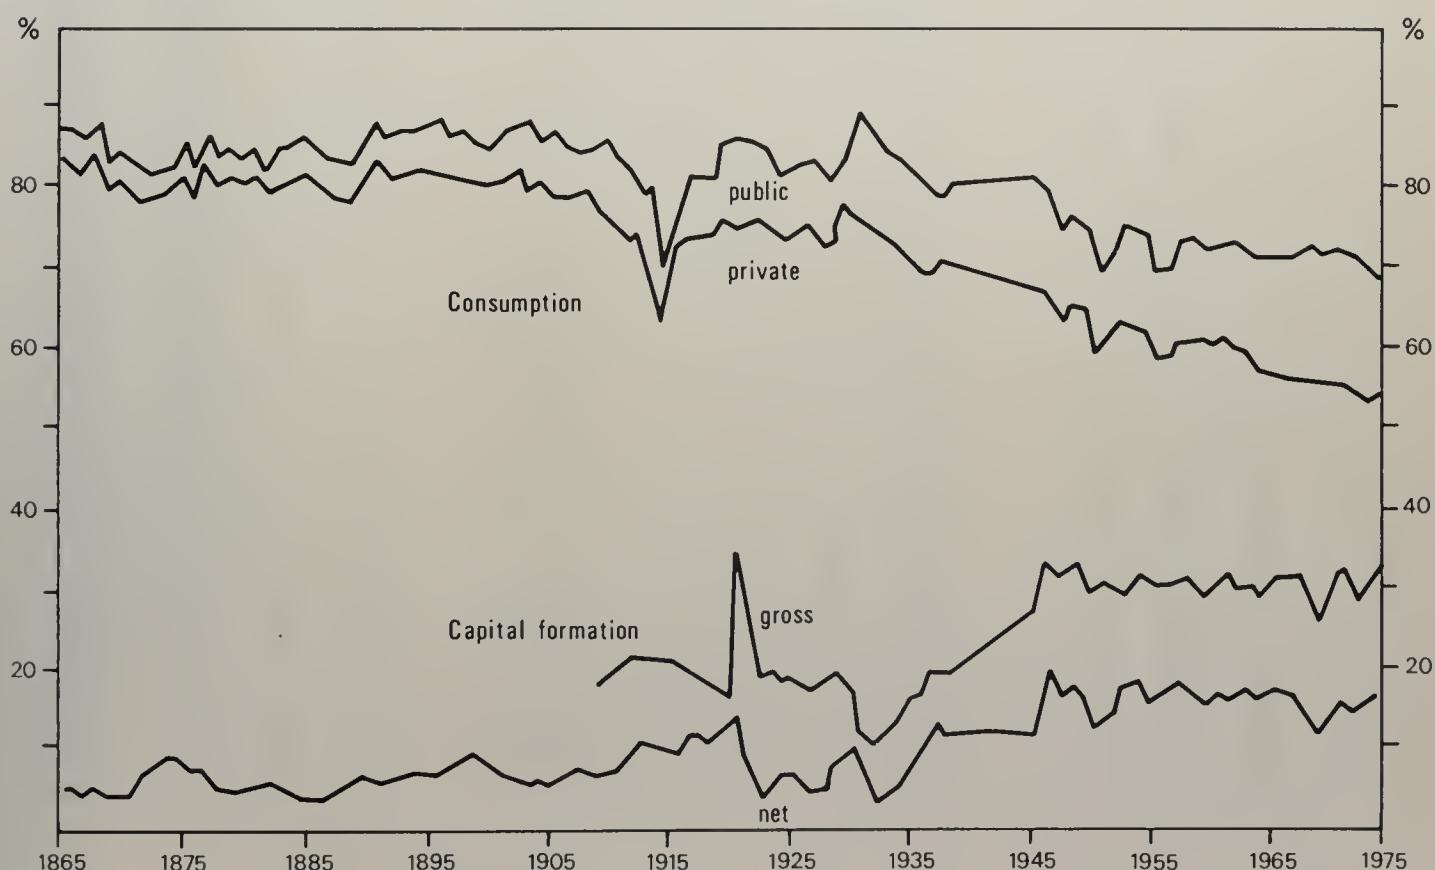

b) Figures for 1865-1950 refer to Gross-GDP. Prior to 1908 without changes in stocks.

c) Prior to 1951 repair and maintenance are included.

a) Figures for 1961-1951 refer to GDP at factor cost.

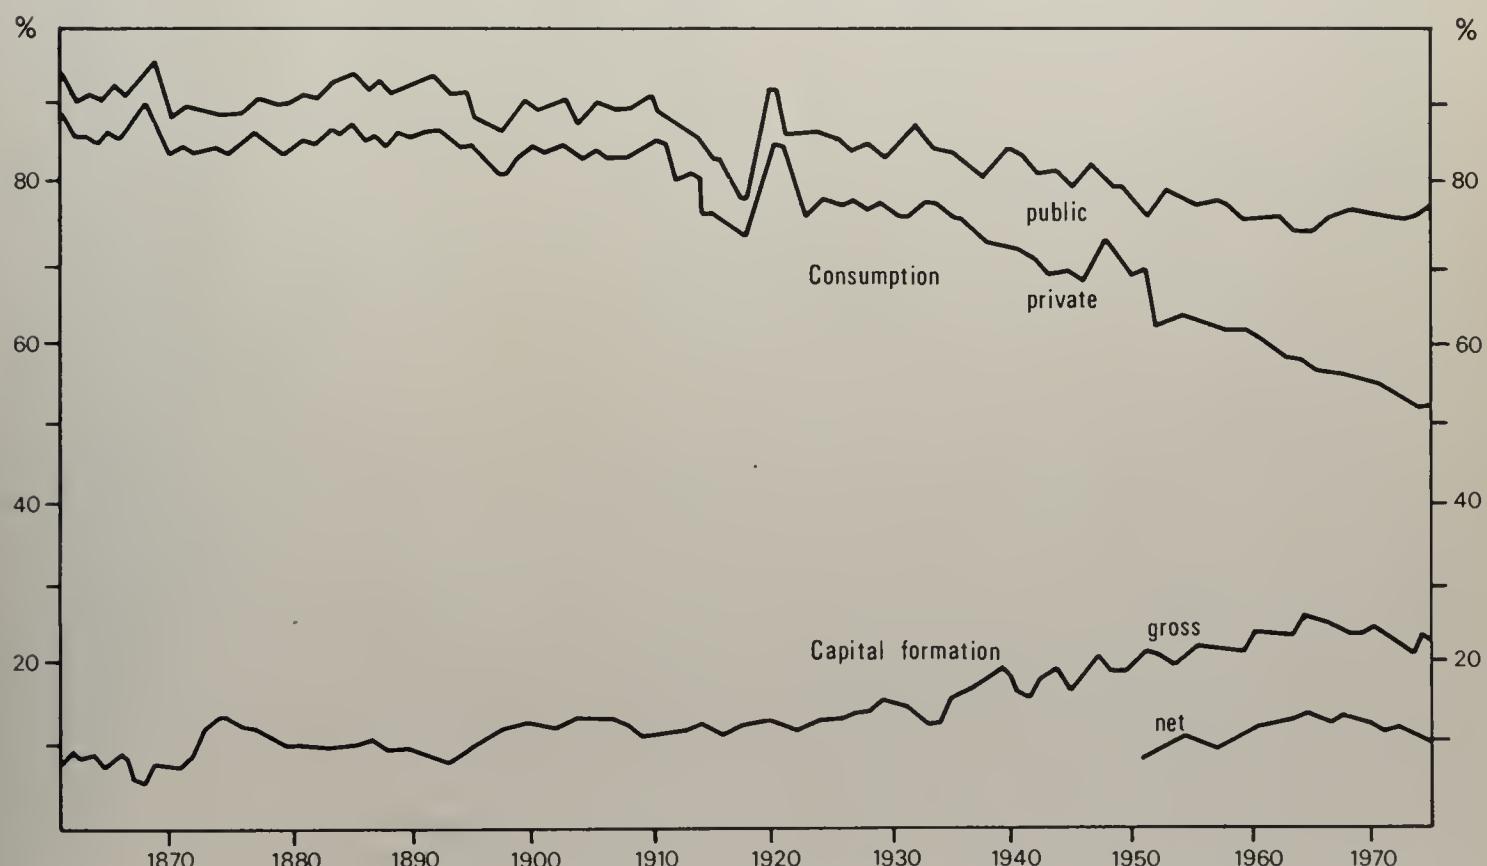

For 1968-1975 market prices are net of value added tax.

b) Prior to 1950 GDP is without changes in stocks.

IX

Division of Labour and Inequality

LABOUR FORCE

This chapter presents basic data on the differentiation of the working population by economic sector and occupational status. This comes perhaps closest to the idea of a 'social structure' of the population as defined by the extent and form of the social division of labour.

One of the earliest attempts to describe the social structure of a country is Gregory King's famous study of the English population in 1688. He classified all English families/households (around 1,35 million with ca. 5,5 million people) by the position of the head of household, distinguishing between 26 social categories. Basically, they represented a mixture of social status (e.g. the distinctions within the gentry), occupation (e.g. merchant), branch of activity (e.g. 'persons in offices'), and industrial status (independents or dependents). He then estimated the average household size and the average annual income per household in each category. Of course, King could not rely on an occupational census, but had to utilize a variety of sources, above all tax statistics.

The first occupational censuses were carried out in the eighteenth century and became a regular practice in the nineteenth century. Up to the last third of the nineteenth century it was common to ask only for the occupation of the head of the family/household as the main provider and to classify the other family/household members (including domestic personnel) accordingly. Only gradually a clearer distinction was drawn between the main breadwinner and the others, until it was finally required to state the occupation of all persons who worked for pay or profit. This transition from counting families to the enumeration of individuals, and the increasing differentiation between occupation, branch and status is a watershed in the history of the occupational census. In principle, the enumeration of individuals instead of families now makes it possible to identify the working population out of the total population of a country. For this reason we have not tried to include censuses prior to around 1880.

In modern censuses, the economically active population is classified according to:

- a) occupation, i.e. the kind of work from which a person earns his main income and/or in which he spends most of his work time,
- b) the branch or industry in which a person pursues his occupation,
- c) industrial status, i.e. the role a person assumes within his place of work such as employer, employee, apprentice etc.

This threefold classification must be seen as a product of a long-term process of increasing differentiation between the three dimensions. Originally, a mixed classification in which occupational aspects predominated was common. Frequently as a first step, the classification by status became more clearly separated, whereas an unambiguous distinction between the occupational and the industrial principle of classification was not normally made prior to World War I.

This differentiation between an occupational and an industrial principle was enhanced by the introduction of industrial censuses in which data are collected on the basis of productive units such as firms, and not on the basis of households as in the case of general population and/or occupational censuses. These special censuses frequently produce figures on the size and structure of the economically active population which differ markedly from those of the general censuses. On the one hand, industrial censuses may underestimate the working population, not only because they are usually partial enumerations, but also because they focus on clearly defined productive units. On the other hand, they may also overestimate the economically active population, because they enumerate positions and not persons, and persons may have more than one occupation.

We therefore have relied exclusively on general censuses. These are mainly general population censuses and only in a few cases separate occupational censuses which also cover the total population (see the following table for all censuses which have been utilized). The main data presented in this chapter refer to the classifi-

cation of the economically active population by branch or sector of activity and by industrial status (cross-tabulations). The classification by occupation has been excluded because it poses insurmountable problems of comparability, even for the period after World War II.

(a) For censuses in brackets, only classifications by sector are available.

Unless due care is exercised, comparisons of labour force statistics over time and across countries may be rendered wholly invalid. It starts with the relatively simple difficulties of an 'operational-statistical' nature. Thus, a first problem stems from differences in the definition of the total population: the choice between utilization of the present or the resident population, and the choice between including or excluding foreigners, has consequences not only for the size of the economically active population, but also for its structure. The size of the labour force may be influenced by the definition of a minimum age (usually varying from nine to fifteen years), because young people under this age limit are automatically excluded even if they are 'economically active'. The census date may also have an impact, since no distinction is normally made between 'permanent' and 'occasional/seasonal' work at the time of the census.

More serious, however, are the conceptual problems in comparing labour force statistics. They refer first of all to the term 'economically active', which must be regarded in terms of the specific organization of work in a particular society. To some extent, therefore, the economically active population will always remain a statistical artifact which should be defined differently for different purposes. However, the conceptual problems refer more to the concept's boundaries and less to its core, because there is a structural equivalent to the statistical artifact: the process of capitalist industrialization has made the labour force more visible as a distinctive population category. Labour and its products are increasingly exchanged in markets, and 'economically active' has largely become synonymous with 'active in markets'. This process of commercialization was related to an increasing separation of household and work place, and to a corresponding spatial and temporal concentration of the working population.

The following figure shows the major classification problems of the labour force concept (here used interchangeably with the concepts of 'economically active population' or 'working population'). The core of the economically active population consists of all those who are gainfully occupied full-time as employees, self-employed or employers in the private or public sector.

A first category of boundary problems refers to the required duration and regularity of this gainful occupation, i.e. the treatment of those who work part-time, who are temporarily out of work, or who are looking for a job for the first time. In this respect the comparability is very limited. Definitions vary greatly and are often vague, and their operationalization and the actual coding are frequently unknown. Usually, all persons whose work only contributes to a minor degree to their living are excluded. Definitions of minimum weekly working hours are found only in recent censuses and vary a great deal. Any such criteria is, of course, relatively arbitrary and must be regarded in terms of the existing social division of labour. With the spread of gainful part-time work, this boundary problem will become even more problematic. In historical perspective, however, the differences in the treatment of persons temporarily out of work are probably more relevant. In early censuses it was frequently the case that all persons who had worked at any point in time were included among the working population (i.e. also retired people). Later, pensioners, invalids, persons in hospitals or other institutional households were excluded. This has also been done in our tables. The two most important categories of people 'temporarily out of work' which have usually been included are the sick and the unemployed. In early censuses the treatment of unemployed persons is frequently unknown, but after the turn of the century they are normally included, even though they were only coded separately later on. Today, there is still the problem of how to distinguish between temporary and long-term sickness and unemployment, and how to classify the — usually young — persons who are unemployed without previous occupation.

A second category of boundary problems refers to the element of 'gainful' work, i.e. the exchange of labour or its product for income. This produces difficulties in all situations in which economic exchange is incomplete or mixed. The most problematic cases are found in private households which have remained productive units, above all in agriculture, among artisans, and in the retail trade. The most frequent census categories, which of course simplify a great variety of work forms in these households, are 'housewives', 'family workers', and 'domestic personnel'. Whenever available as separate categories, housewives have been excluded from the economically active population, and domestic personnel have been classified as workers in the service sector.

The classification of family workers, who may be paid or unpaid family members or other relatives, is much more problematic. The actual treatment has varied greatly and these differences pose enormous problems for comparability. Sometimes it is not even known whether family workers are included or not; sometimes they are included but their classification is unknown; and sometimes they are coded as workers or as self-employed or are distributed among the various status categories.

With respect to the 'gainful' aspect of work, boundary problems are not only created by the differentiation of private households and units of production. They are also produced by the differentiation of the educational system and the labour market, and by the development of public institutional households. As to the educational system, pupils and students are consistently excluded, but apprentices in part-time voca-

tional schools are classified as economically active, and as a separate category where the relevant information was available. Among the persons working in public institutional households without corresponding pay, only conscripts have usually been included, all others (e.g. prisoners) being classified as economically inactive.

This introduction is only intended as a brief explanation of our general guidelines in delineating the economically active population, and its indicates only the most serious problems encountered in comparing labour force statistics. Some additional information can be found in the notes to the tables, but more complete information will only be given in the computer documentation.

For altogether 131 censuses, the data are presented in a standard table in which the total labour force is classified according to ten sectors of economic activity, six status categories, and sex (separate data are given for the male labour force only).

The classification of economic activities relies on the UN International Standard Industrial Classification (ISIC), with a few modifications:

- (1) The ISIC category 'services' has been split into a general service sector and into public administration.
- (2) Some activities have been reclassified in order to create more homogeneous sectors. The most important cases are given in the following table.

Classification of economic activities by sector

I	Agriculture:	agriculture forestry fishing
II	Mining:	mining quarrying
III	Manufacturing:	basic mineral products basic metal products fabricated metal products, machinery and equipment fabricated non-metallic mineral products chemicals, rubber and plastic products paper, printing and publishing furniture and wood products textiles, wearing apparel and leather products food, beverage, and tobacco other manufacturing industries
IV	Construction:	building construction of communication networks
V	Utilities:	electricity, gas and steam water works and supply
VI	Commerce:	wholesale trade retail trade
VII	Transport:	transport and storage communication
VIII	Banking:	banking insurance (except social security institutions)
IX	Services:	restaurants and hotels (ISIC: VI) laundry, cleaning, repair, sanitary services domestic services real estate and business services (ISIC: VIII)

		private non-profit organizations
		recreational and cultural services
		education
		health
		social security institutions
		religion
		international organizations and extraterritorial bodies
X	Public ad- ministration:	civil administration police military
XI	Unknown	industry unknown not adequately described (not: unknown whether active or not)

This standard classification has been applied to all 131 censuses. Differences in the definition of sectors could be minimized by regrouping the economic activities on the basis of the most detailed census table. With few exceptions, therefore, the actual classification comes very close to the above standard classification. Where problems arise, they are mainly found in delimiting mining and manufacturing, in creating a utility sector (often included in other sectors), and a more homogeneous banking sector (which often includes very heterogeneous activities).

The transition from occupational to industrial classification entails a break in the series. Whenever possible, occupational classifications have been transformed into pseudo-industrial classifications, which assume that certain types of occupations are typically performed in a specific industry. This presupposes a low level of vertical integration of production. While the resulting figures are fairly reliable for a distinction between the primary (I), secondary (II to V), and tertiary sectors (VI to X), they are far less reliable for more detailed analyses. This holds especially true for the tertiary sector.

The classification of day-labourers varies considerably between censuses. Sometimes they are considered a separate category, and sometimes they are assigned to the temporary occupation at census time or their dominant occupation during the previous year. They account for a large proportion of 'industry unknown' in our tables.

With respect to status, no standard classification could be applied because the definition of status categories differs markedly between censuses. Whenever possible, data have been re-arranged to meet the following distinctions:

Definitions of status categories

Employers	those employing other than family workers
Self-employed	those working on their own account without help except for family workers
Employees	higher-status dependent labourer or white collar personnel, including civil servants
Workers	lower-status dependent labourers or blue collar personnel, including home-workers
Apprentices	persons in vocational training in firms
Family Workers	assisting spouses, children or relatives

With respect to the comparability of these status categories, three general observations can be made:

(1) The major distinction between an independent labour force (employers and self-employed) and a dependent labour force (employees and workers) is fairly consistent and comparable. Sometimes managers and directors are included among the employers, but this bias is not very significant.

(2) Within these two major groups, however, the categories are not strictly comparable. This is especially true for the distinction between workers and employees which, to a varying degree, combines differences in the type of work (manual versus non-manual), the work place (factory versus office), and the legal status (in labour and social security law). Here, comparisons must be limited to relatively stable contexts.

(3) In general, data on family workers are much less reliable and comparable than for any other category because their definition and coverage varies greatly (which sometimes causes breaks in comparability even for the figures on 'total labour force').

For some of the earlier censuses, it is not possible to cross-tabulate the labour force by sector and status, but only to give separate totals for the different categories. These data are included in the summary table for each country which precedes the census tables.

The summary table gives an overview with respect to the development of:

- (a) the total labour force and the activity ratios;
- (b) the distribution of the labour force among the three major sectors: the primary (sector I), secondary (II-IV), and tertiary (VI-X) sectors;
- (c) the distribution of the labour force among dependent, independent, and family workers;
- (d) the domestic personnel and military personnel.

Data on the two specific groups in (d) have been included in order to improve the comparability of the two sectors Services (IX) and Administration (X). With regard to the latter, the classification of conscripts differs from one census to another. Sometimes they have been included in the sector, sometimes they have been excluded from the labour force. In many censuses, however, they have been coded according to their previous status and sector of activity. Thus, on the basis of the figures given in the summary table, it is possible to construct a more comparable public administration sector by excluding the military personnel.

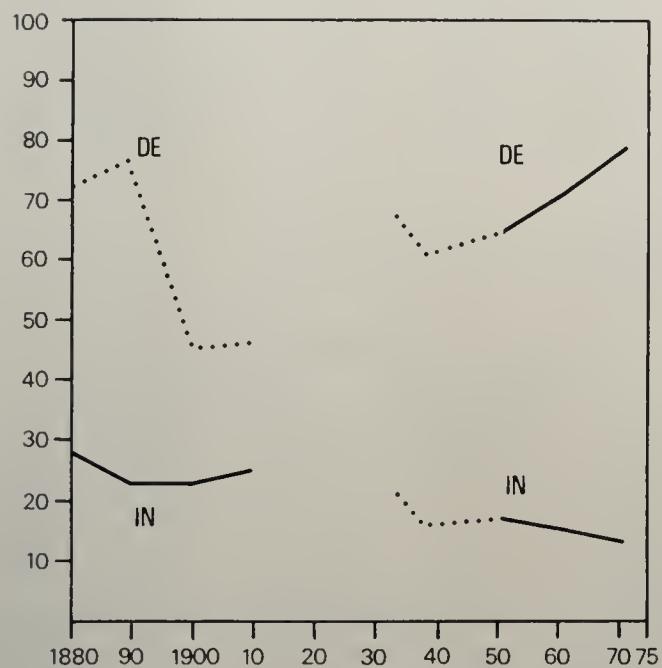

The sector Services poses still greater problems. It comprises much more heterogeneous activities than any other sector and one may doubt whether it is meaningful to group all these activities together. In order to reduce the heterogeneity somewhat, we give separate figures for the domestic personnel as they form a distinctive and, in earlier times, quantitatively important group within the service sector. However, we have not done what would have been necessary: to reclassify the various activities according to a more detailed and theoretically meaningful classification scheme (as suggested for example by Siegelman in his book *From Agriculture to Services. The Transformation of Industrial Employment*. London: Sage 1978). Such a reclassification would have required a separate project which we are glad to leave to all people who are crazy enough to follow us.

Notes:

- 1880-1910 Present population aged 10 years and over
- 1880 a) Included mainly among Workers
 b) Including conscripts
 c) Including a large proportion of day-labourers
- 1890 a) Included mainly among Workers
 b) Including conscripts
- 1900 a) Restricted enumeration as compared to 1880 and 1890
 b) Including conscripts
- 1910 a) Including conscripts
- 1934-1971 Resident population
- 1934-1939 Unemployed classified according to their previous occupation; conscripts included in the public sector
- 1951-1971 Conscripts and unemployed classified according to their previous occupation; persons seeking work for the first time excluded from the labour force
- 1934 a) Excluding persons under the age of 14 (except those living outside the parental household) and domestic servants of economically non-active persons
 b) Including civil servants
 c) In agriculture all persons aged 14 to 60 classified as family workers, except housewives, sick persons and those in vocational training
 d) Including conscripts
- 1939 a) German census for the territory of the former Austrian Republic
 b) Including enterprises under military control
 c) Including conscripts
- 1951 a) Including civil servants
 b) Farmers' wives are classified as family workers, except for large land-holdings
- 1961 a) Including civil servants
 b) Farmers' wives classified as family workers
- 1971 a) Persons aged 15 years and over working at least 14 hours a week
 b) Including civil servants
 c) Farmers' wives included only if explicitly stated that they assist their husbands
 d) Included among Employees or Workers

Notes:

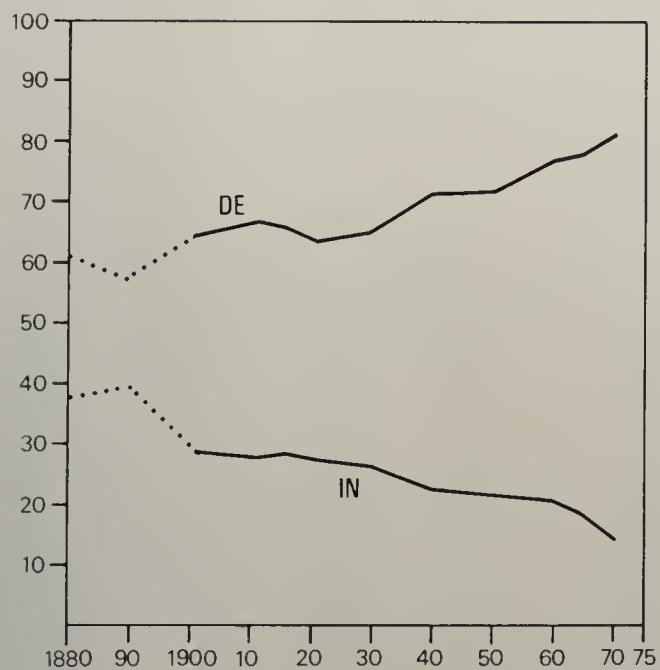

- 1880-1970 Resident population of age 15 and over (1880-1961) and of age 14 and over (1970)
- 1880-1900 Labour force refers to jobs and not to persons; the status distribution must be regarded as a crude estimate
- 1930-1970 Conscripts included under Public Administration
- 1947-1970 Unemployed as separate census category included under Unknown
- 1880-1900
- a) Status distribution partially estimated; in Commerce, the percentage distribution of the 1910 census has been used; in Services and Public Administration, the distribution has been inferred from the nature of occupation
 - b) Not included in the labour force
 - c) Including conscripts
 - d) No separate figures available
- 1910-1920
- a) Status distribution for Services and Public Administration partially estimated on the basis of the nature of occupation; conscripts allocated according to their previous occupation
- 1930
- a) Unemployed classified according to their previous occupation
 - b) Including directors and managers
 - c) For liberal professions, status partially inferred from the nature of occupation
 - d) Including military personnel
- 1947
- a) Including directors and managers
 - b) Including home-workers
 - c) Including military personnel
 - d) Mainly unemployed
- 1961
- a) Including home-workers
 - b) Including military personnel
 - c) Mainly unemployed
- 1970
- a) Including conscripts
 - b) Mainly unemployed

Notes:

- 1880-1970 Resident population
- 1880-1930 Status classification in Services and Public Administration not directly available; classification partially inferred from the nature of the respective occupation/sector
- 1880
- a) Including the Faeroe Islands
 - b) Servants engaged in domestic services and/or production activities
 - c) Included in the labour force (except for assisting married females), but classification unknown
 - d) Included in Manufacturing
 - e) Mainly day-labourers
- 1890
- a) Servants engaged in domestic services and/or production activities
 - b) Included in the labour force (except for assisting married females), but classification unknown
 - c) Included in Manufacturing
 - d) Mainly day-labourers
- 1901
- a) Including apprentices
 - b) Included in the labour force, but only if living by their own means
 - c) Excluding assisting married females
- 1911
- a) Including apprentices
 - b) Included in the labour force, but only if living by their own means
 - c) Excluding assisting married females
- 1916
- a) Excluding all married females and conscripts; status classification in Agriculture, Banking, Services, and Public Administration according to the 1921 classification system
 - b) Including family workers
- 1921
- a) Excluding all married females
 - b) Including family workers and apprentices
- 1930
- a) Including workers and family workers; distinction between workers and employees available for certain sectors only
 - b) Including family workers
 - c) Excluding assisting married females
- 1940-1970
- a) Including assisting married females, but excluding assisting children
 - b) Including conscripts

Notes:

- 1910-1940 Skilled employees included among the independent labour force, unskilled employees among Workers
- 1910 a) Quarrying included under Manufacturing
- 1920-1930 a) Extensive definition of agricultural family workers as compared to 1910
b) Quarrying included under Manufacturing
- 1950 a) Definition not comparable to previous and later censuses
- 1960 a) Including Self-employed
- 1970 a) Apprentices included among Workers

Notes:

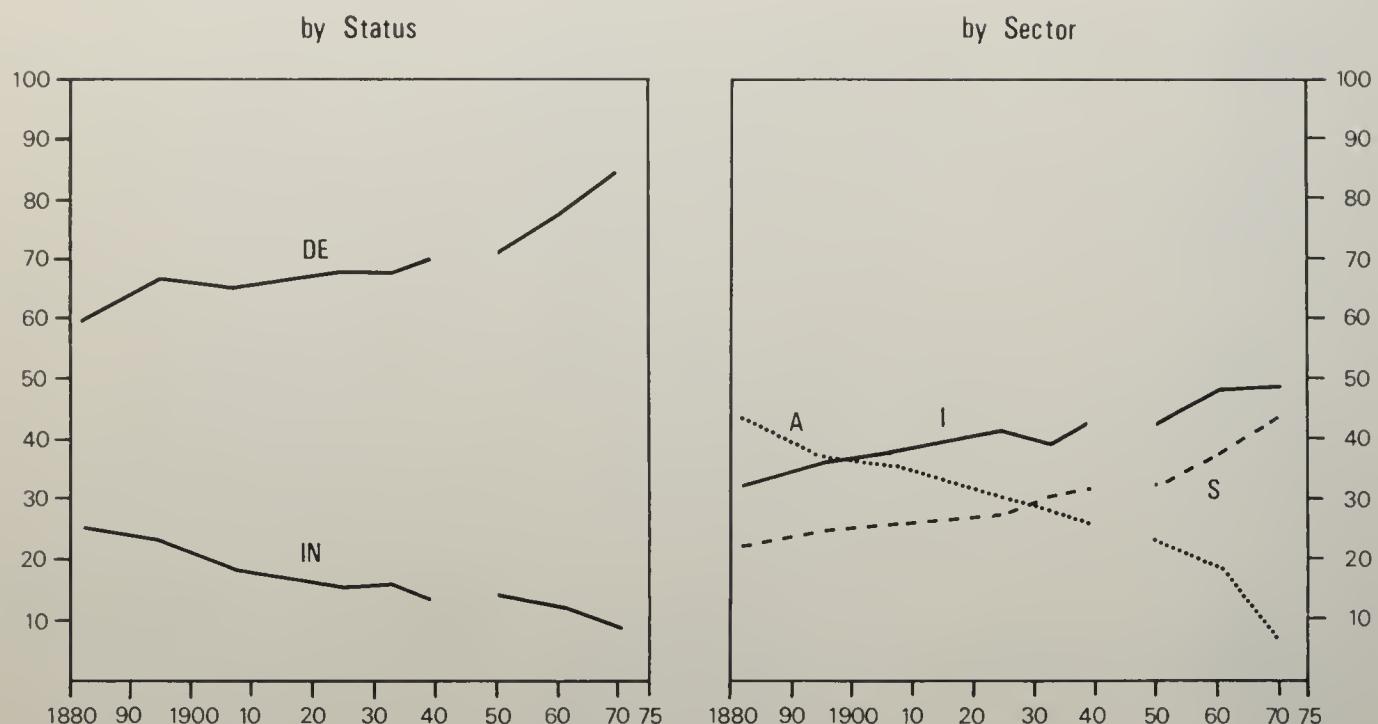

- 1886-1891 Excluding persons classified as having no profession, non-classified persons and profession unknown
- 1896-1968 Services public généraux, i.e. enterprises under state control, here classified under the appropriate sector, if they employ a sizeable work force
- 1896-1906 Present population without specific age limit
- 1921-1975 Present population, excluding persons working abroad but with residence in France, and persons working in France but with residence abroad
- 1881
 - a) Included under Manufacturing
 - b) Included under Commerce
 - c) Persons classified in the census as independent have been included among Employees, except for military forces
 - d) Including military forces
- 1886
 - a) Including priests and teachers in public schools re-classified as Employees
 - b) Civil servants have been re-classified as Employees
 - c) Military forces classified as Workers
- 1891
 - a) Status classification of some liberal professions inferred from the nature of occupation
 - b) Persons classified in the census as independent re-classified as Employees, except for military forces
 - c) Including military forces
- 1896
 - a) First special occupational census; change in the method of enumeration largely accounting for the increase in the total labour force; excluding 23,559 persons of unknown sex
 - b) Travailleurs isolés: self-employed, casual workers, and home-workers
 - c) Chômeurs: persons out of work due to unemployment, sickness and invalidity
 - d) Estimated minimum number calculated by subtracting from the total number of employers the number of establishments with employees; the true number of family workers is higher since many have been classified as employees or workers
- 1901
 - a) Including family workers classified as employers
 - b) Travailleurs indépendants, partially estimated from the census category travailleurs isolés
 - c) Including workers
 - d) Salariés à emploi irrégulier, partially estimated from the census category travailleurs isolés
 - e) Ouvriers à domicile, partially estimated from the census category travailleurs isolés
 - f) see 1896 note (d)
 - g) Persons out of work due to unemployment, sickness and invalidity
- 1906-1936
 - a) Including family workers classified as employers
 - b) Travailleurs indépendants, partially estimated from the census category travailleurs isolés
 - c) Salariés à emploi irrégulier, partially estimated from the census category travailleurs isolés
 - d) see 1896 note (d)
 - e) Persons out of work due to unemployment, sickness and invalidity
- 1946
 - a) Combination of a highly aggregate table and more detailed tables for some sectors; classification by sector not strictly comparable to previous censuses
 - b) Including managers and high ranking civil servants
 - c) Only certain activities under Services and Public Administration (teachers, civil servants) could be classified as Employees; in other sectors they had to be classified as Workers
 - d) Only family workers in Agriculture could be classified; they are included among Workers
 - e) Including employees and family workers
 - f) Excluding some activities classified in the Public Administration sector

- g) Including some activities which should be classified under Services or under Manufacturing (enterprises under state control)
 - h) Including some activities previously classified under Services and Transport
- 1954
- a) Excluding conscripts (ca 200,000); work force in Agriculture more strictly defined than in previous censuses; according to the older enumeration method the work force would be higher by 1.2 million
 - b) Including managers and high ranking civil servants
 - c) Including priests classified as independent in the census
 - d) Including some liberal professions classified under Services in previous censuses
- 1962-1968
- a) Excluding conscripts (1962: ca 581,000, 1968: ca 243,000)
 - b) Including managers and high ranking civil servants
 - c) Including priests classified as independent in the census
 - d) Including some liberal professions classified under Services in previous censuses
- 1975
- a) Excluding conscripts whose exact number is unknown; classification by sector inferred from a relatively aggregate table; sectors VI-X not strictly comparable to previous censuses
 - b) Including managers and high ranking civil servants
 - c) Including priests classified as independent in the census
 - d) Including certain activities which should be classified under Services (education) or Manufacturing (enterprises under state control)

Notes:

- 1882-1907 Present population beyond compulsory education (about 14 years and over); occupational classification for skilled workers and some liberal professions; otherwise industrial classification
- 1927-1970 Resident population; pure industrial classification
- 1933-1961 Including unemployed
- 1882
- a) Status distribution for Commerce, Services, Transport, and above all Public Administration partially based on a re-classification of status categories according to nature of occupation
 - b) Including directors
 - c) Including apprentices, family workers, and home-workers
 - d) Included among Workers
 - e) Separate figures available for Agriculture only
 - f) In Agriculture: small peasants working also as agricultural day labourers; in Services: some liberal professions for which a status classification according to the nature of occupation would have been too arbitrary (e.g. musicians)
 - g) Including conscripts
 - h) Mainly day labourers
- 1895
- a) Status distribution for Services partially based on classification according to nature of occupation; in Public Administration those originally classified as Employers have been re-classified as Employees or Workers according to the nature of occupation
 - b) Including directors
 - c) Including some apprentices
 - d) Including some apprentices and all home-workers
 - e) In Agriculture classified as employees; in the other sectors distributed among employees and workers
 - f) Including conscripts
- 1907
- a) see 1895 note (a)
 - b) Including self-employed
 - c) Including high ranking officials
 - d) Including some apprentices
 - e) Including some apprentices and all home-workers, originally classified as self-employed
 - f) Distributed among employees and workers
 - g) In Agriculture: small peasants working also as agricultural day labourers; in Services: some liberal professions for which a status classification according to the nature of occupation would have been too arbitrary
 - h) Including conscripts
 - i) Mainly day labourers without main occupation
- 1925
- a) Change in territory
 - b) Including self-employed
 - c) Including high ranking officials
 - d) Including skilled and unskilled workers as well as home-workers, originally classified as self-employed
 - e) Excluding conscripts who were classified according to their previous occupation
- 1933
- a) Excluding the Saar
 - b) Including self-employed but excluding managers and high ranking officials classified as independents in the census
 - c) Civil servants including high ranking officials
 - d) Including managers
 - e) Including conscripts and commissioned officers

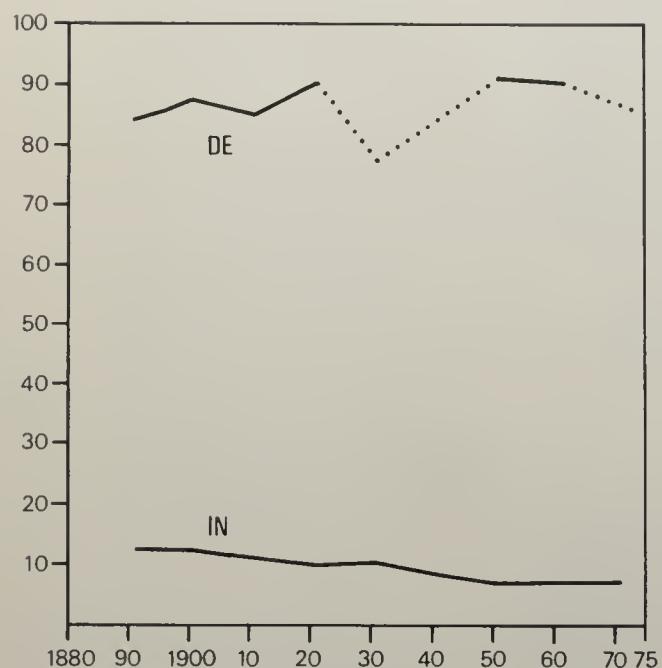

- 1939 a) Including the Saar, but excluding Austria and the Sudetenland
 b) Including self-employed
 c) Civil servants including high ranking officials
 d) Including managers
 e) Including commissioned and non-commissioned officers, and volunteers
 f) Including conscripts
 g) Including enterprises under military control
- 1950 a) Excluding West Berlin and the Saar; excluding foreign military forces in West Germany
 b) Including self-employed
 c) Civil servants
- 1961 a) Including West Berlin and the Saar; since original data are rounded, rounding errors may occur
 b) Including self-employed
 c) Civil servants
 d) Commercial and industrial apprentices
- 1970 a) Excluding the unemployed; excluding foreign military forces in West Germany and their families;
 including part-time work
 b) Civil servants
 c) Including all military personnel (officers and conscripts)

Notes:

Great Britain

Population of age 10 and over (1891-1911), age 12 and over (1921), age 14 and over (1931), age 15 and over (1951-1971)

- 1891-1901 Mixed industrial-occupational classification; most people classified by industry; persons who are classified according to their occupation only (the most important cases being: 'clerks in business'; 'engine drivers'; porters and messengers) are usually included under 'sector unknown'
- 1911 Different classification for England/Wales and Scotland; see notes below
- 1921 Mainly occupational classification
- 1931-1971 Purely industrial classification
- 1971
- a) Resident population; including part-time workers; figures calculated on the basis of the reported 10% sample of census returns, by simply multiplying the reported figures by 10
 - b) Foremen, supervisors, professional employees and apprentices
 - c) Included in the labour force, but classification unknown
 - d) Mainly persons out of work whose previous status/sector is unknown (total: 1,288.9, males: 852.3)

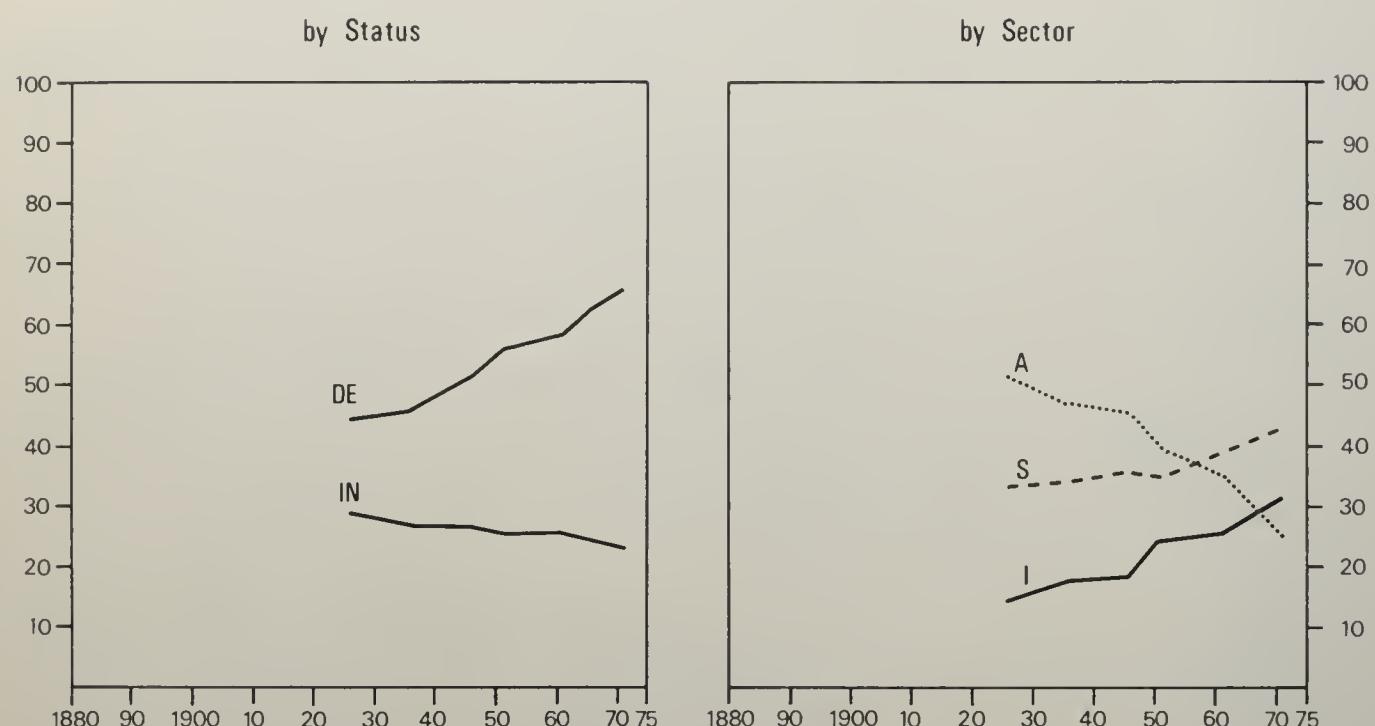

England and Wales

- 1891
- a) First census with classification by status; low quality of returns
 - b) Including self-employed
 - c) Included in the labour force, but classification unknown
 - d) Excluded from the labour force because of inadequate coverage
- 1901
- a) Including self-employed
 - b) Included in the labour force, but classification unknown
 - c) Excluded from the labour force because of inadequate coverage
- 1911
- a) Mixed industrial-occupational classification; see general notes
 - b) Including self-employed
 - c) Assisting children and other relatives in Agriculture only; other family workers not included in the labour force
 - d) Mainly porters, messengers and warehousemen
- 1921
- a) Occupational classification used, because only this classification is cross-tabulated with classification by status
 - b) Assisting children and other relatives in Agriculture only; other family workers are not included in the labour force
- 1931
- a) Including directors and higher management
 - b) Branch and departmental managers, originally included among Employers; all other employees included among Workers
 - c) Workers and employees; see note (b)
 - d) Unknown whether included in the labour force
 - e) Unemployed and temporarily ill persons, previously not included in the labour force
- 1951
- a) Including part-time work (ca 747,000 persons)
 - b) Directors, higher and middle management only; all other employees included among Workers
 - c) Workers and employees; see note (b)
 - d) Included among workers
 - e) Included among workers; separate figures are low, because assisting housewives are probably included among part-time workers

- 1961 a) Including part-time work (ca. 1.9 million persons)
 b) Managers, foremen and supervisors (manual and non-manual), professional employees; all other employees included among Workers
 c) Workers and employees; see note (b)
 d) Probably included among Workers
 e) Including persons out of work due to unemployment and illness
- Scotland
- 1891 a) Including self-employed
 b) Included in the labour force, but classification unknown
 c) Not included in the labour force
- 1901 a) Including self-employed
 b) Including home-workers (domestic industrial work)
 c) Assisting children and other relatives in Agriculture only; other family workers are not included in the labour force
- 1911 a) New industrial classification principle, not used in England and Wales; distribution by sector fairly comparable with previous censuses, but very limited comparability with 1921 occupational census
 b) Assisting children and other relatives in Agriculture only; other family workers not included in the labour force
- 1921 a) Occupational classification used in order to make a comparison with England and Wales possible; however, in contrast to England and Wales, a cross-tabulation of the classifications by industry and status also exists
 b) Assisting children and other relatives in Agriculture only; other family workers are not included in the labour force
- 1931 a) Including directors and higher management
 b) Branch and departmental managers, originally included among Employers; all other employees included among Workers
 c) Workers and employees; see note (b)
 d) Unknown whether included in the labour force
- 1951 a) Including part-time work (130,540 persons)
 b) Managers, foremen and supervisors, professional employees; all other employees included among Workers
 c) Workers and employees; see note (b)

Notes

- 1926-1971 Present population of age 12 and over (1926) and of age 14 and over (1936-1971)
- 1926-1949 Including persons classified as Out of Work (unemployed, ill at home, etc.) but excluding persons in hospitals, etc.
- 1951-1971 Including persons classified as Out of Work (unemployed, ill at home, etc.) and persons temporarily in hospitals and similar institutions
- 1926 a) Including ca. 1,200 persons who were too old to work (age 70 and above) and some retired persons
- 1936 a) Including some central government employees; probably, unclarified error in source
- 1946 a) Including company directors, but excluding other persons classified as managers who are included among Employees
- 1951 a) Including all managers
b) Including persons temporarily in hospitals and similar institutions
- 1961 a) Excluding persons temporarily in hospitals and similar institutions who are allocated to their respective status category

Notes:

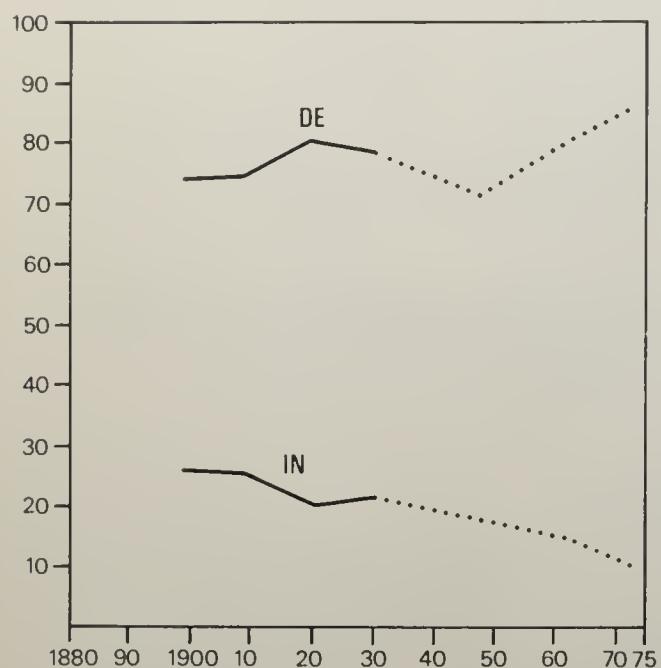

1881-1901	Present population of 9 years of age and over
1911-1936	Present population of 10 years of age and over
1951	Resident population of 10 years of age and over
1961-1971	Resident population of 14 years of age and over
1881-1921	Conscripts included in the public sector
1931-1971	Conscripts distributed according to their previous occupation
1881-1921	Unemployed probably classified according to their previous occupation
1931-1971	Unemployed classified according to their previous occupation
1881	a) Status classification in Agriculture and sectors VI-X partially inferred from the nature of occupation b) Unknown whether included in the labour force c) Included under Manufacturing and Construction
1901	a) Status classification in Agriculture and sectors VI-X partially inferred from the nature of occupation b) Including managers c) Craftsmen; may also be dependent labourers d) No distinction possible between employees and workers e) Probably included among Employers
1911	a) Status classification outside Manufacturing partially inferred from the nature of occupation; partially estimated in Transport and Construction b) Domestic servants active in production c) Probably included among the independent labour force
1921	a) Including managers b) Probably included among the independent labour force c) Status classification in Agriculture inferred from the type of activity performed d) Status classification inferred from the nature of occupation
1931	a) Including managers b) Originally included in the various status categories; calculated using a table with fewer, aggregated sectors, but a separate category of family workers c) Status classification in Agriculture inferred from the type of activity performed d) Status classification inferred from the nature of occupation
1936	a) Including managers and high ranking civil servants b) Including home-workers c) Mainly domestic servants, including those active in production d) Mainly persons seeking work for the first time
1951,1971	a) Including self-employed liberal professionals b) Including home-workers c) Only persons seeking work for the first time d) Excluding state-run firm holdings
1961	a) Including self-employed liberal professionals, directors of business firms and high ranking civil servants b) Including home-workers c) Only persons seeking work for the first time d) Excluding state-run firm holdings

Notes:

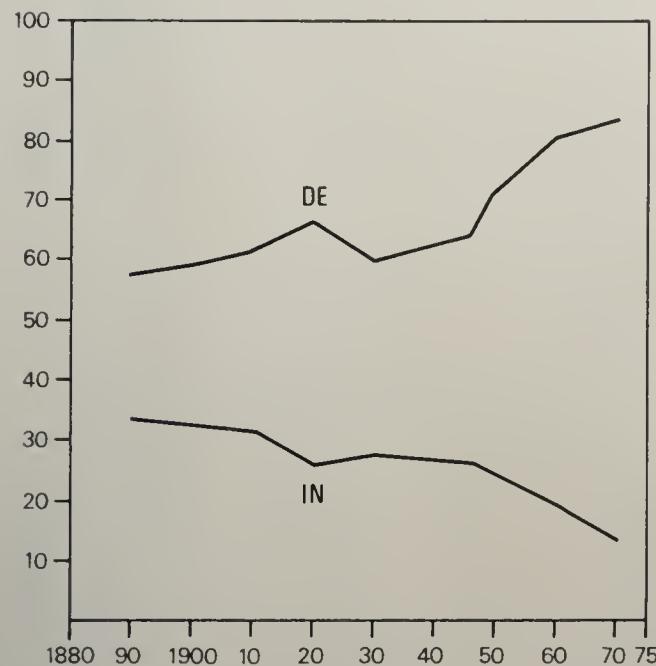

- 1899-1971 Present population; unemployed classified according to previous occupation
- 1899
- a) The status distribution of Public Administration is a crude estimate based on a given status distribution of the aggregate sectors IX and X, after excluding domestic servants
 - b) Including assisting spouses
 - c) All family workers included in the labour force, but classification of unmarried family workers unknown; see note (b)
 - d) Excluding conscripts (who are classified according to their previous occupation)
- 1909
- a) The status distributions of Mining, Utilities, and Public Administration are crude estimates based on the proportions in the 1899 census; see also note (a) for 1899
 - b) Including assisting spouses
 - c) All family workers included in the labour force, but classification of unmarried family workers unknown; see note (b)
 - d) Excluding conscripts (who are classified according to their previous occupation)
- 1920
- a) The status distributions of Mining, Utilities, and Public Administration are crude estimates based on the proportions in the 1930 census; see note (a) for 1930
 - b) Including assisting spouses
 - c) All family workers included in the labour force, but classification of unmarried family workers unknown; see note (b)
 - d) Excluding conscripts (who are classified according to their previous occupation)
- 1930
- a) The status distribution of Public Administration is a crude estimate based on a given status distribution of the aggregate sectors IX and X, after excluding domestic servants
 - b) Including assisting spouses
 - c) All family workers included in the labour force, but classification of unmarried family workers unknown; see note (b)
 - d) Excluding conscripts (who are classified according to their previous occupation)

Notes:

- 1890-1930 Present population aged 15 years and over
- 1946-1970 Resident population aged 15 years and over (1946-1960) or 16 years and over (1970)
- 1890-1920
- a) Including directors and high ranking officials
 - b) Adult children and other relatives in Agriculture; assisting married females not included in the labour force
 - c) Partially included in Manufacturing
 - d) Excluding conscripts (who are classified according to their previous occupation)
- 1930-1946
- a) Including directors and high ranking officials as well as part of the family workers in Agriculture and hotels in sector IX
 - b) Including part of the family workers
 - c) Higher reporting as compared to earlier censuses due to changes in enumeration procedure
- 1950-1960
- a) Including family workers
 - b) Assisting children in Agriculture only; assisting married females not included in the labour force
- 1970
- a) Assisting spouses and children

Notes:

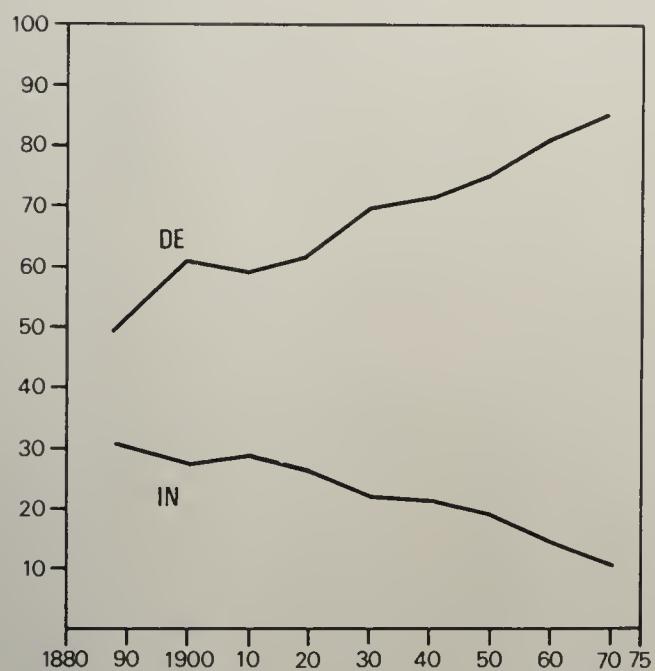

- 1880-1910 Predominantly industrial classification
1920-1970 Pure industrial classification
1880-1920 Status distributions in Agriculture, Services, and Public Administration partially estimated according to the nature of the respective occupation/sector
1880-1950 Conscripts included in the labour force and classified according to their previous occupation
1965-1975 Inclusion of conscripts unknown
- 1880 a) Including family workers
 b) Children over 15 years of age and other relatives; extensive enumeration in Agriculture
 c) The Swedish census category 'tjenstehjon' mainly includes domestic servants, but also servants active in production; male servants in handicrafts (part of sector III), however, are classified as workers; figures are given in brackets because they are not included in the respective totals; see also note (d)
 d) Including, among Workers, all servants
- 1890-1900 a) Including family workers
 b) Children over 15 years of age and other relatives; extensive enumeration in Agriculture
 c) Including, among Workers, all servants (see note c) of 1880), except male servants in handicrafts classified as workers in Manufacturing
- 1910-1920 a) Including family workers
 b) Assisting spouses and children over 15 years of age; more extensive enumeration in Agriculture and rural handicrafts; number of family workers in Agriculture not comparable to previous censuses
 c) Including, among Workers, all servants (see note c) of 1880), except male servants in handicrafts classified as workers in Manufacturing
- 1930 a) Status distributions in Agriculture and Transport partially estimated according to the nature of the respective occupation/sector and the classification system of the 1940 census
 b) Assisting spouses and children over 15 years of age; extensive enumeration in Agriculture
- 1940 a) Assisting spouses and children over 15 years of age; major break in comparability to previous censuses due to a more restrictive enumeration procedure in Agriculture
- 1945 a) Assisting spouses and children over 15 years of age; number of family workers in Agriculture not comparable to previous census due to a further restriction in the enumeration
- 1950 a) Mainly assisting children; largely excluding assisting married females
- 1960 a) Conscripts not included in the labour force
- 1965 a) Persons working at least 20 hours during the census week
 b) No separate figures by sex available
 c) Extended enumeration in Agriculture
- 1970-1975 a) Persons working at least 20 hours during the census week

Notes:

- 1880-1970 Resident population of age 14 and over
1900-1960 Excluding part-time employment
1900-1930 Including unemployed, classified according to their previous occupation
1941-1970 Including unemployed as a separate category
1970 Including part-time employment
- 1880 a) Excluding unemployed
b) Apprentices partially included among the dependent labour force, partially excluded from the labour force due to enumeration problems
- 1900 a) Included in the figures for Employees, Workers and Apprentices
b) Including home-workers
- 1910 a) Including self-employed home-workers
b) Included among Employees and Workers
- 1920 a) Including self-employed home-workers
b) Included in the figures for Employees, Workers and Apprentices
c) Including persons in public institutional households working at the time of the census
- 1930 a) Including home-workers
b) Including persons in public institutional households working at the time of the census
- 1941 a) Including home-workers
b) Including persons in public institutional households working at the time of the census; including unemployed, in earlier censuses distributed according to their previous occupation
- 1950-1960 a) Including home-workers
b) Including some private, state-approved reform schools
c) see 1941 note (b)
- 1970 a) Including home-workers
b) Including unemployed

INCOME DISTRIBUTION

This chapter provides data on the distribution of national income by factor shares and on the distribution of personal income by size of income. Data on the distribution of national income come from national account statistics. Data on the distribution of personal income are mainly derived from income tax statistics; in a few cases, they are taken from country studies.

For the classical economists, the most important inequalities of income were those originating from the division of the national product between land and capital on the one hand, and labour on the other. For these economists, the community was correspondingly composed of three classes: landowners, capitalists, and labourers. Compared with the high incomes coming from property (first from land and then increasingly from commercial and industrial capital), income differences within the propertyless labour class seemed negligible. Marx even expected that income differences within classes would diminish and those between them would increase.

This expectation was misleading in several respects. As a long-term trend, the proportion of property income in national income has fallen. Correspondingly, the share of income from work has increased, not only as a consequence of the rise in the share of employees in the total labour force, but also because of the greater investment in maintaining and increasing the quality of labour. In addition, the spread between higher and lower earnings from labour has become wider due to the relative growth of technical and professional labour, and the increase in number of managers and officials in large-scale public and private enterprise. Thus, in general the variance of personal income today is more attributable to inequalities of earnings than to the inequality of property-holding.

The chapter contains two tables for most countries. The first gives data on the distribution of net domestic product at factor cost (by economic institution, type of income, and income position). Net domestic product is defined as gross domestic product minus capital consumption (depreciation) and minus the net balance of indirect taxes and subsidies or – equivalently – as the sum of all factor incomes (for the absolute figures, see chapter 5). For the purpose of this chapter, the difference between the net domestic product at factor cost and the national income, which includes the net balance of factor payments to and from abroad, is negligible.

The first table shows the percentage distribution of net domestic product among the three categories of 'factor cost': compensation of employees, income of entrepreneurs, and income from property. Whereas the first category is relatively clear, the distinction between the two others is problematic. Income from property usually includes property income of households (dividends, interest, money rents, and rents imputed on owner-occupied housing), net profits of corporations (after payment of dividends but before payment of direct taxes), and property and entrepreneurial income of government. It does not include, however, the capital component of the total income of unincorporated entrepreneurs and self-employed persons. Any allocation of this total income between a compensation of entrepreneurial work and a return on capital is necessarily arbitrary to a large extent.

Several indicators of income inequality can be calculated on the basis of the distribution of national income by factor costs. All of them are based on an assumed identity of functional categories with social classes: the 'compensation of employees' is equalized with the total income of the dependent labour force, and the income from entrepreneurial labour and from property is equalized with the total income of employers and self-employed. This procedure is problematic for two reasons both of which refer to the category of 'property income'. Firstly, workers and employees may also have income from property, and this is increasingly true at least since World War II. Secondly, this category also includes retained profits of corporations and property income of government which are not distributed to private households.

For both reasons, there is a tendency to overestimate the total income of employers and self-employed, especially in more recent periods. No attempt has been made to divide up the property income between

entrepreneurs and the dependent labour force, because only slightly different assumptions lead to widely discrepant estimates. We have excluded, however, the property income of government as far as possible (see notes to tables) and then calculated two series: the first by excluding retained profits of corporations, the second by allocating them to the independent labour force. The first table therefore gives the distribution of net domestic product at factor cost by group of recipients (private households, corporations, government).

The relative shares of the two 'social classes' in national income are of course dependent on their relative size. Any meaningful indicator has to take this into account. The first table therefore includes the percentage shares of the dependent labour force in the total labour force (excluding for the sake of greater comparability the category of 'family workers'). For census years these percentages are based on the census figures given in the preceding chapter. For the intercensus years they have been simply interpolated (except for the years around World War I and II for which they have been extrapolated forwards and backwards).

Two principal indicators of inequality have been calculated: the 'wage-profit ratio' and the 'standardized labour's share' (which is more adequately known also as the 'standardized share of compensation'). Both indicators attempt to separate distributional changes from changes in the status composition of the labour force.

The 'wage-profit ratio' compares the 'average dependent income' (compensation of employees divided by the dependent labour force) with the 'average independent income' (income from entrepreneurship and property divided by the number of employers and self-employed). The 'standardized labour's share' instead compares the 'average dependent income' with the 'average national income' (national income divided by the total labour force) and is simply calculated by dividing the share of the compensation of employees in national income (the so-called labour's share) by the share of the dependent labour force in the total labour force (both shares given in the first table). Instead of comparing average incomes one may exclude the status effects by assuming constancy of the status composition. Such an index of the 'hypothetical labour's share' is calculated by multiplying the 'standardized labour's share' by the share of the dependent labour force in the total labour force of a common reference year (here 1970).

These measures (which may point in different directions) give a general indication of the relative income position of the two major 'social classes', workers and employees on the one hand, and employers and self-employed on the other. This is true at least for the period prior to World War II when the property income of the dependent labour force and the retained profits of corporations as well as government property income were relatively insignificant. For a more realistic picture of income inequality, however, the internal heterogeneity of the two 'classes' is too great. This heterogeneity has certainly increased within the dependent labour force due to the relative growth of white-collar occupations. It has probably decreased among employers and self-employed due to the relative decline of agriculture and the concentration process in trade and commerce.

For a more comprehensive and detailed account of the distribution of personal income one has to turn to income tax statistics. These are the only source for an analysis of long-term changes, because the other major source, sample surveys, only covers more recent periods. Income tax statistics usually provide the following information for a varying number of nominal income classes: the number of income tax units, the income, and the assessed taxes (or class specific tax rates). Much less information can be found in these statistics on the distribution of income by occupation and/or economic status or other criteria. In a more systematic way, such information is available only for Austria, Germany, and the Scandinavian countries. These data are not given here, but will be included in a separate handbook (see below).

The second table therefore gives data only on the distribution of pre-tax income among individuals (or other income units) without reference to their socio-economic characteristics. In principle, the data should refer to the incomes that flow directly out of participation in the production process, but in practice they do this only approximately. Especially in earlier times, tax statistics do not provide figures on gross income but only on taxable or even taxed income. The variations in tax exemption levels, deductible items and tax allowances pose a problem of comparability, at least prior to World War II. But even if gross income figures are given, they usually do not include income equivalents such as fringe benefits or retained profits. On the other hand, they may include taxable transfer payments. Among these transfer elements we have generally excluded pensions.

Other problems of cross-national and intertemporal comparability of tax-derived income distribution data arise from differences in the definition of income units and from the varying coverage of income taxation.

It is, individuals who participate in the production process, but in tax statistics the reported income units may be individuals, married couples, or even a mixture of both. This is due to variations in tax legislation (above all in the definition of the tax unit) and differences in publication practices of the statistical offices. The traditional unit of income taxation was the economic household with its aggregate income. In former times a very broad household concept was frequently used which included not only the income of children, but also of other relatives living within the household. More restricted variants of household taxation which confine taxation to the nuclear family have been in existence in France, Italy, and above all in Belgium until the 1970s. In other Western European countries joint taxation (of earned income) has been restricted to married couples for some time now. In the last two decades, however, the individual is increasingly taken as the unit of taxation (in some countries compulsory, in others still optional).

No comparison can be made between income distribution data based on the extended household concept and those based on the individual and/or married couple as tax unit. For this reason the former data have not been included, and Belgium had to be excluded altogether. But even then the problems of comparing the incomes of individuals and couples remain. Fortunately, since World War II, tax returns are increasingly given not only for the respective 'tax units' but also for individuals, and this information may be used for an evaluation of 'mixed' distributions. The synopsis on the following page therefore shows for the relevant countries the respective units of taxation, the units for which statistics are reported, and the share of joint assessments.

A historical analysis of the distribution of personal income requires income tax statistics, but not all income tax systems are equally suitable. The modern European income taxes developed from two types: scheduled taxes and lump-sum taxes (see the following historical synopsis). The scheduled income tax is a set of taxes on different types of income which are not added together to form a person's total income. Very often only certain types of incomes were taxed (partial scheduled income tax). Pure scheduled taxes no longer exist. They have either been supplemented by a personal income tax or replaced by a general personal income tax. The lump-sum income tax, on the other hand, was from the very beginning a tax on an individual's income, although it was often confined to earned income (partial income tax). Only supplementary income taxes and general personal income taxes cover the incomes from all sources and thus provide sufficient information on the size distribution of personal income.

The Introduction of Income Tax Systems

COUNTRY	SCHEDULE TAXES		LUMP-SUM TAXES		
	Partial Schedule Tax	Schedule Tax	Partial Personal Income Tax	Supplementary Personal Income Tax	General Personal Income Tax
Austria	1849–1896				
Belgium		1919/20–1962		1919/20–1962	
Denmark					1810–44, 70–72, 1903–
Finland					1865–81, 1929–
France	1872–1917	1918–1959			1960–
Germany					1920–
Prussia			1812–14, 51–72		1873–1919

U.K.		1803–16, 42–1918		1910–18, 52–	1799–1802, 1918–

The different timing of the introduction of modern income tax systems sets historical limits to a comparative study of income inequality and the different treatment of married couples creates considerable conceptual problems, but the greatest impediment to comparability lies in the varying coverage of income taxation. The synopsis on the following page shows the percentages of taxed persons in the total labour force (in cases of joint taxation of couples the number of single persons has been estimated). It shows that prior to World War II high coverage was the exception rather than the rule. For the interwar period, income distribution can be compared cross-nationally for the upper 50 percent of income recipients at most, while prior to World War I only the upper 10 percent (or even less) can be compared. The major exception from this general trend is Ireland, where the recently introduced super-tax covers only a few top recipients.

It is obvious that income distributions can only be compared for comparable segments of the – often unknown – complete distribution. An attempt has therefore been made to improve the comparability by estimating the total number of tax units on the basis of the labour force statistics in Chapter 7. Excluding family workers and domestic servants from the total labour force, the remaining number of economically active persons has been adjusted to the definition of the units in income tax statistics (for explanations, see notes to the second table). On the basis of the estimated total number of tax units, so-called quantile ratios (see below) have then been calculated.

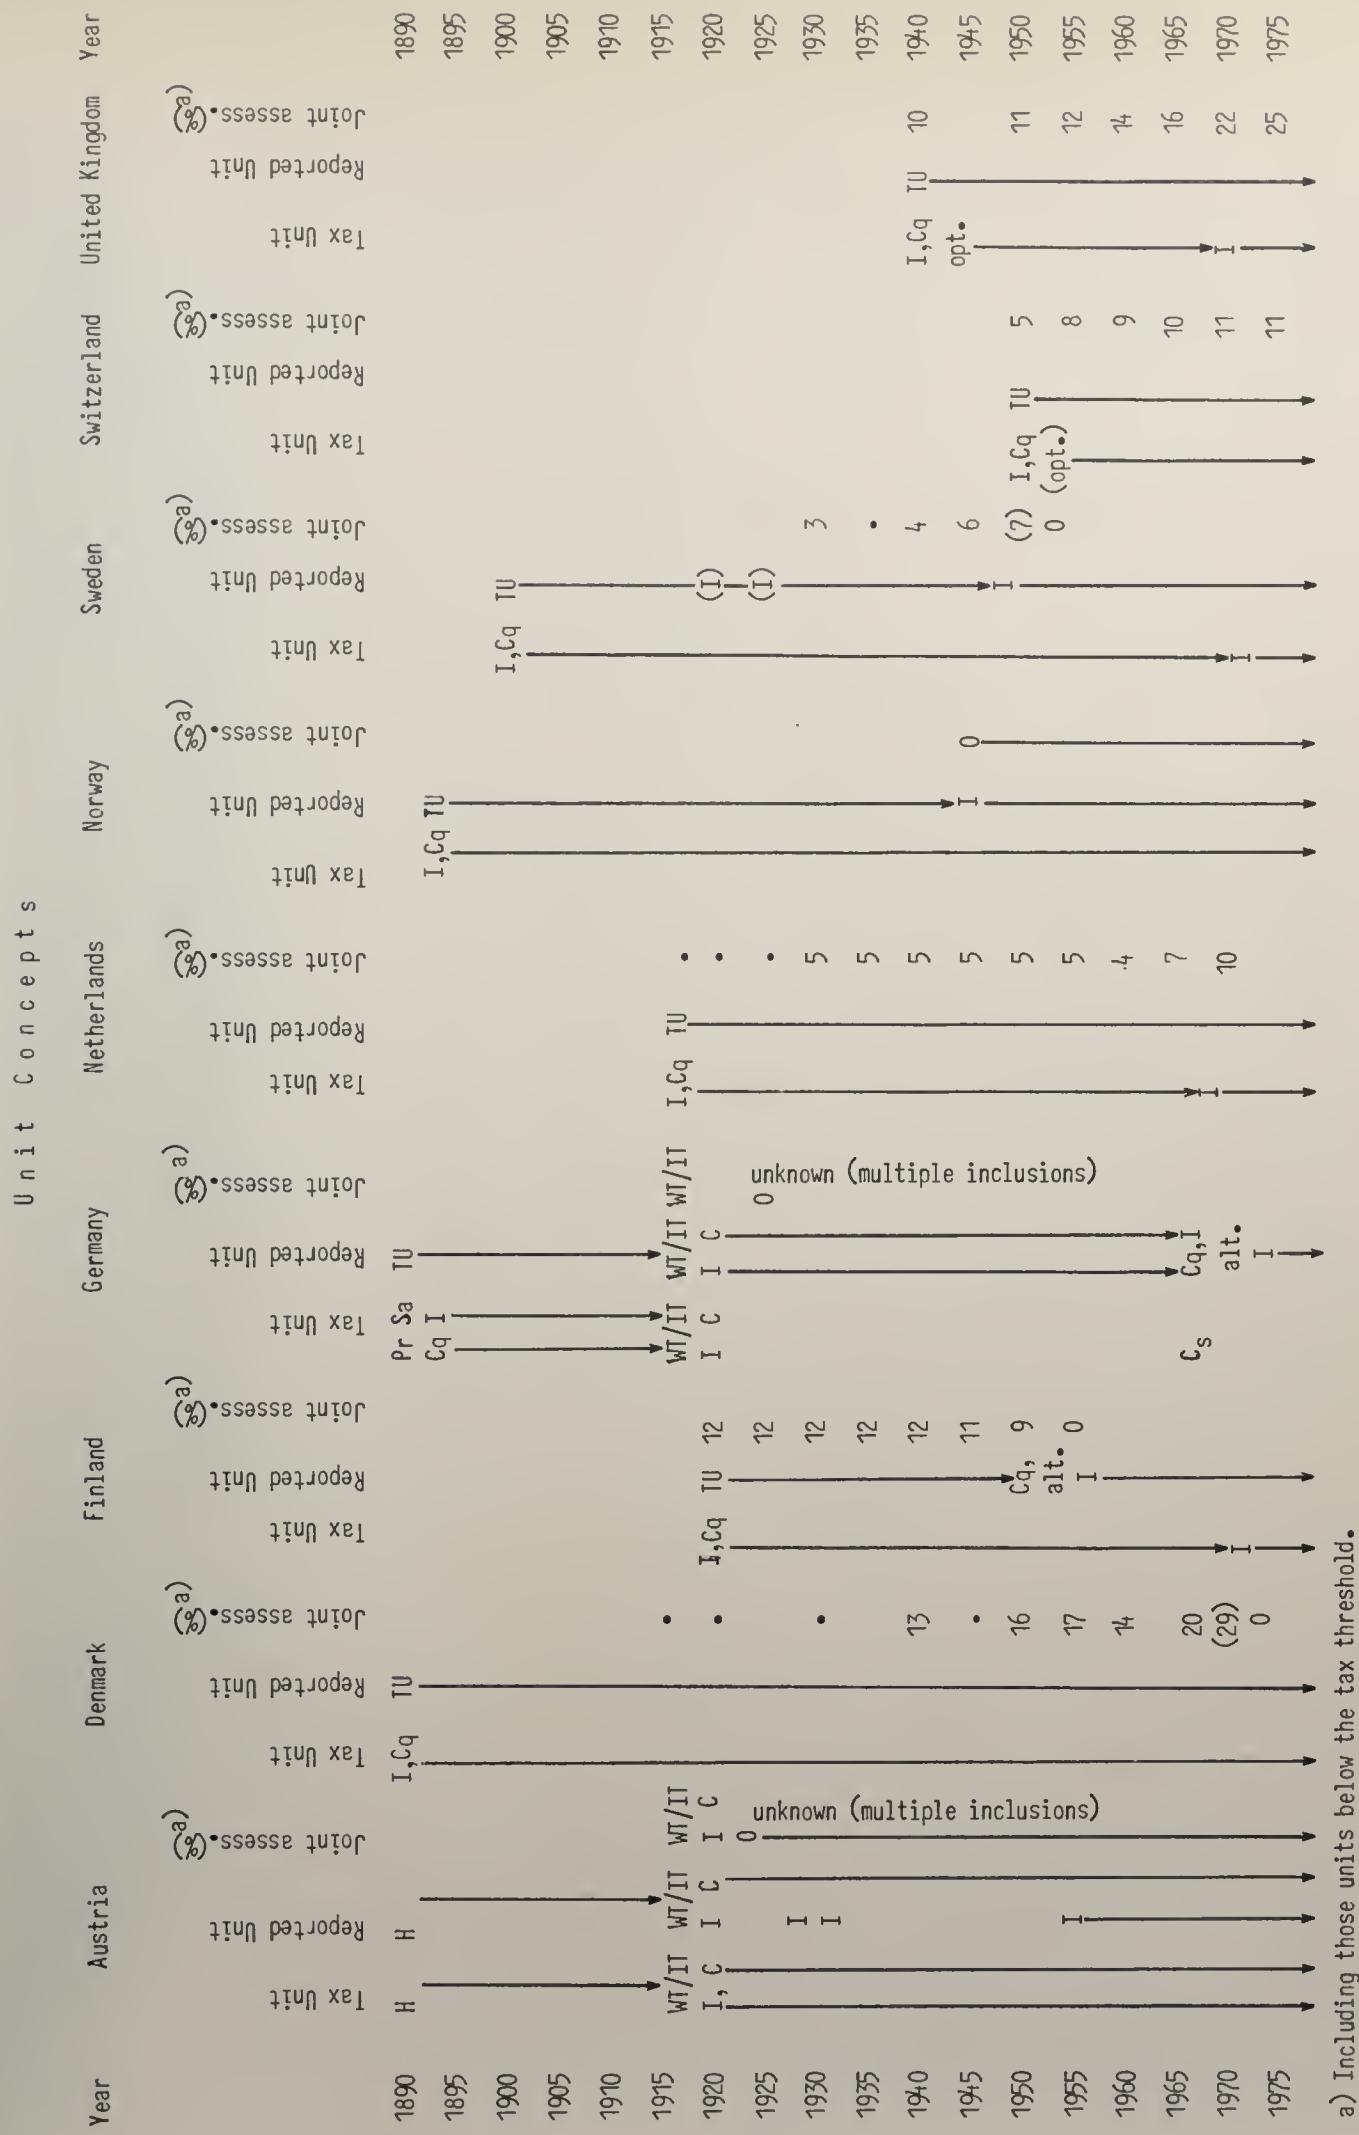

The second table presents indicators of the structure and degree of income inequality. This is the only section of the handbook where the coverage is limited to less than 13 countries: Belgium had to be excluded because it uses the extended household concept, Ireland because of its pre-modern income tax system, Italy (where data have only been published in recent years) and France because of the low and strongly biased income coverage. Of the remaining nine countries, the structure of income inequality is measured in terms of quantile ratios and fractile shares, and the degree of income inequality in terms of the Gini index and the maximum equalization percentage. The table also provides information on the type of tax unit, the types of reported income units, and the share of couples as well as of economically active married females in the total labour force.

Quantile ratios and fractile shares are both based on a ranking of 'income units' (individuals or couples) by the size of their income. If one takes an income at a certain point of this income hierarchy (e.g. the income of the recipient which marks 75 percent of the ranked recipients) and relates it to a 'typical income' such as the median (i.e. the income of the recipient which divides the distribution of all recipients in half) or the average income, one arrives at quantile ratios (e.g. the percentile ratio 75). If one takes instead a certain segment of the income hierarchy (e.g. the top 10 percent income earners) and relates it to the total income, one arrives at fractile shares (e.g. the income share of the top decile). Fractile shares are superior in the sense that they incorporate more information, whereas quantile ratios have the advantage that they can be calculated on the basis of incomplete information.

The Gini index (known also as the normalized relative mean difference) is derived from a cumulative income distribution which is based on a ranking of all individuals (or other tax units) according to their income. Starting from those with the lowest income, a line is drawn representing the total percentage of income received by increasingly larger percentages of all income receivers: the so-called Lorenz curve. In the case of complete equality, this curve would be a 45-degree line. The area between this hypothetical line and the actual Lorenz curve may be used as an indication of income inequality. Dividing this 'area of inequality' by its maximum size (defined by the case where one person receives the total income) gives the Gini index which ranges between 0 (complete equality) and 1 (maximum inequality).

The maximum equalization percentage (also known as the normalized relative mean deviation) is based on a division of all (ranked) income recipients into two groups (of usually varying size) so that each of them receives half of the total income. It gives the share of total income which would have to be redistributed from the top to the bottom group in order to obtain perfect equality. It therefore is only sensitive to distributional changes between two groups, whereas the Gini index is sensitive to distributional changes over the whole income range. On the other hand, an interpretation of changes in income inequality in terms of Gini indexes may be problematic when Lorenz curves cross-cut each other.

All the indicators of the structure and degree of income inequality had to be calculated on the basis of grouped data. Income tax statistics provide the number of income recipients and their total income only for a limited (and varying) number of income classes (usually, however, for many more than ten and sometimes even more than 100 classes). For the computation of quantile ratios and fractile shares (here in form of deciles) one has to group income classes together, and – in order to get specific quantiles/fractiles – to split up some of them.

a) Including those units below the tax threshold.

For those income classes which had to be divided, the internal distribution was estimated by logarithmic interpolation. The Gini coefficients have been calculated on the basis of these (partly estimated) income deciles — under the conservative assumption of perfect income equality within the deciles. Therefore, they represent lower limits of inequality which are fairly comparable across countries and over time.

Income distribution data certainly belong to the most complex and problematic statistics. Even a cautious interpretation would require more information and additional data. These will be provided in a separate handbook by Franz Kraus, to be published in 1986. It will contain a systematic discussion of sources (tax statistics as well as surveys), a survey of basic measures (including a historical summary of measurement approaches), and additional series of disaggregated and more sophisticated data on income inequality.

Sources:

1976-1953 Statistics on wage-tax.
1933, 1928 Special investigation of the Austrian Statistical Bureau, published in Statistische Nachrichten, Vienna 1953.

Population: The series only refers to employment incomes of employees and workers (largely excl. of family workers). Data include a small amount of double countings.

Income:

1976-1953 Gross income.
1933, 1928 Estimated full-time gross incomes.

Coverage: Tax units as % of employees and workers (excl. family workers).

Adjustment to improper coverage:

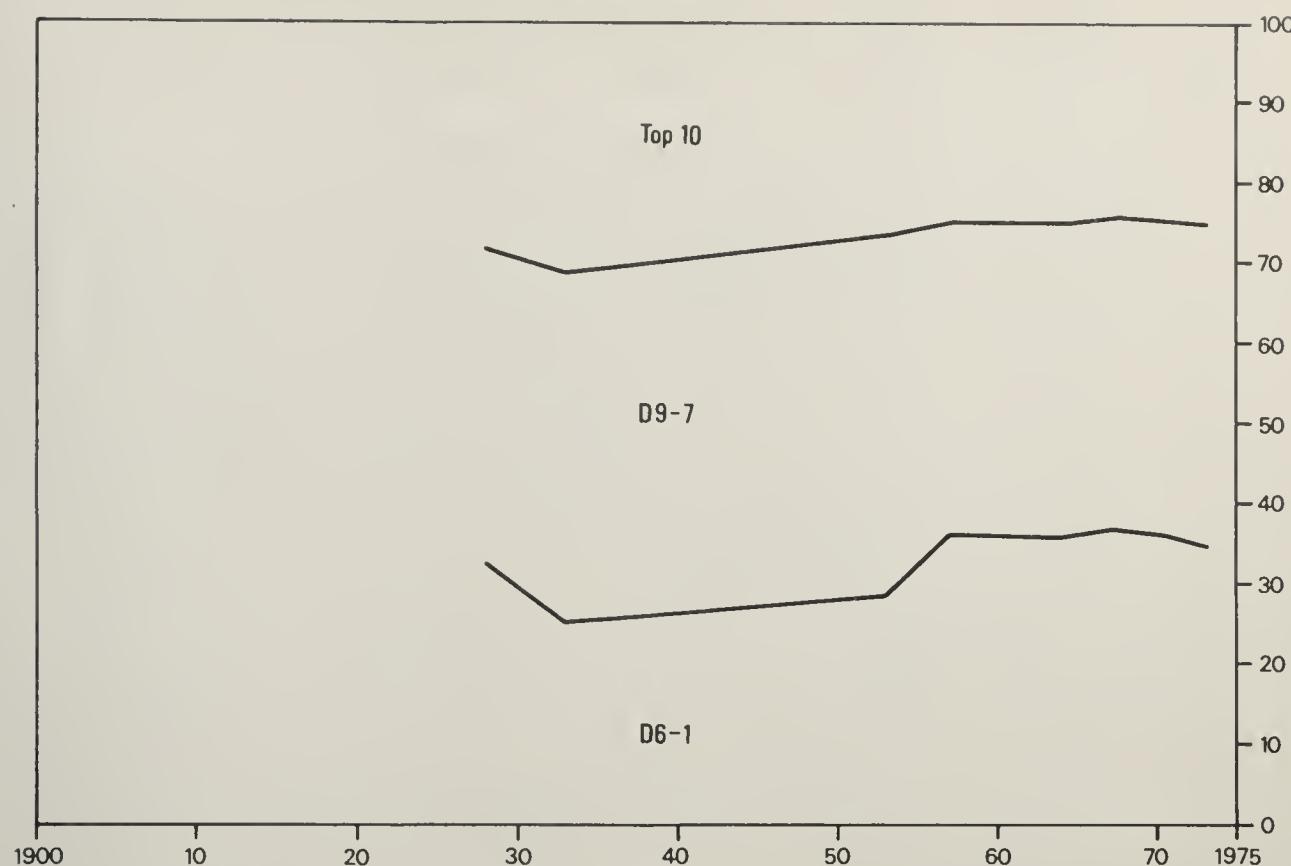

1976-1953 No adjustment because improper coverage is not due to the existence of an income threshold.

1933, 1928 Estimate for units below the reported income limit of 1400 Austrian Shillings.

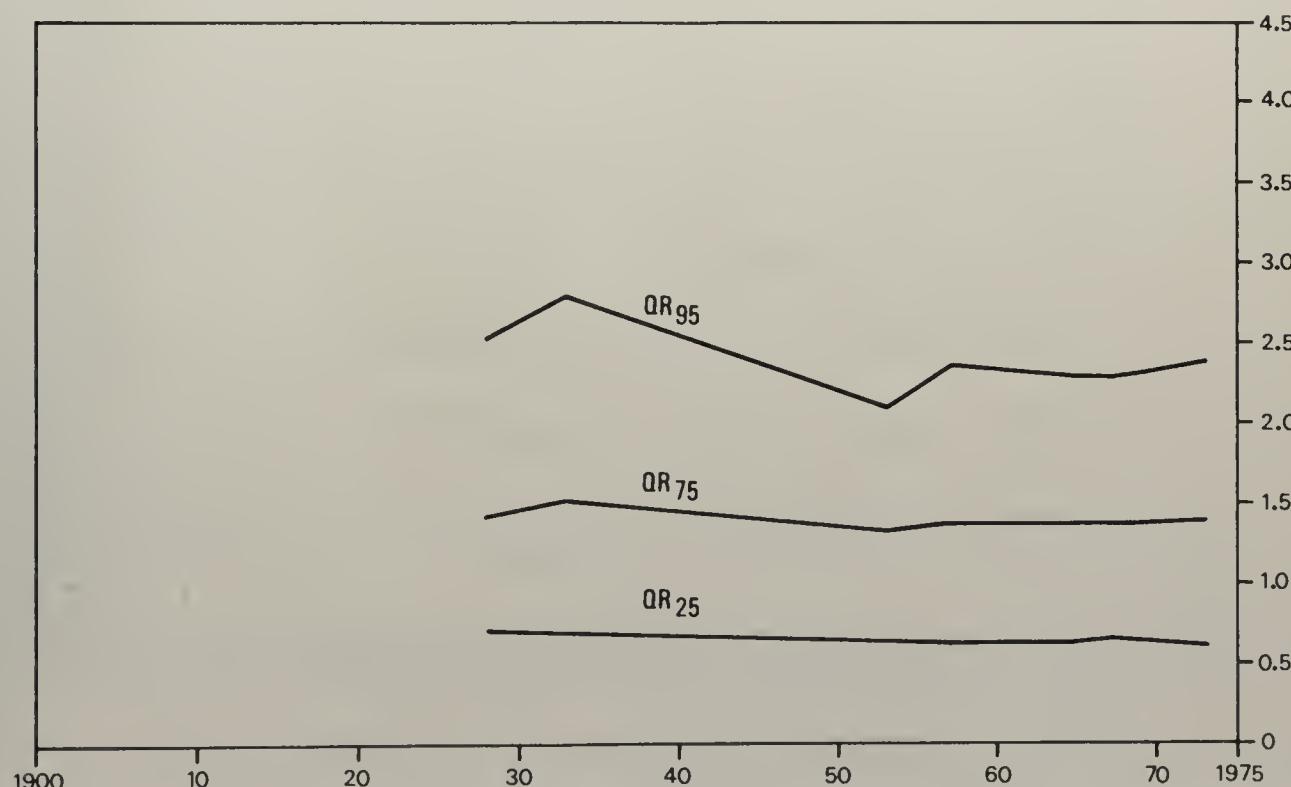

- a) Different population concept: employees and workers after exclusion of pensioners. Cf. note 2).
- b) Different population concept: employees and workers after the exclusion of substantial parts of pensioners and recipients of old-age benefits.
- c) Break in comparability. Cf. general note on income concepts.
- d) After adjustment for improper coverage of employees and workers (1933: 588 000 units, 1928: 385 000 units).
Figures tend to overestimate inequality.
- e) Employees and workers incl. of pensioners with an income of Austrian Shillings 1400 and over.

Sources: Tax statistics and population censuses.

Population:
1976-1939 Labour force excl. of the category 'Unknown'.
1938-1916 Labour force plus renters and parts of the pensioners.

Income:
1976 Gross income.
Prev. years Taxable income.

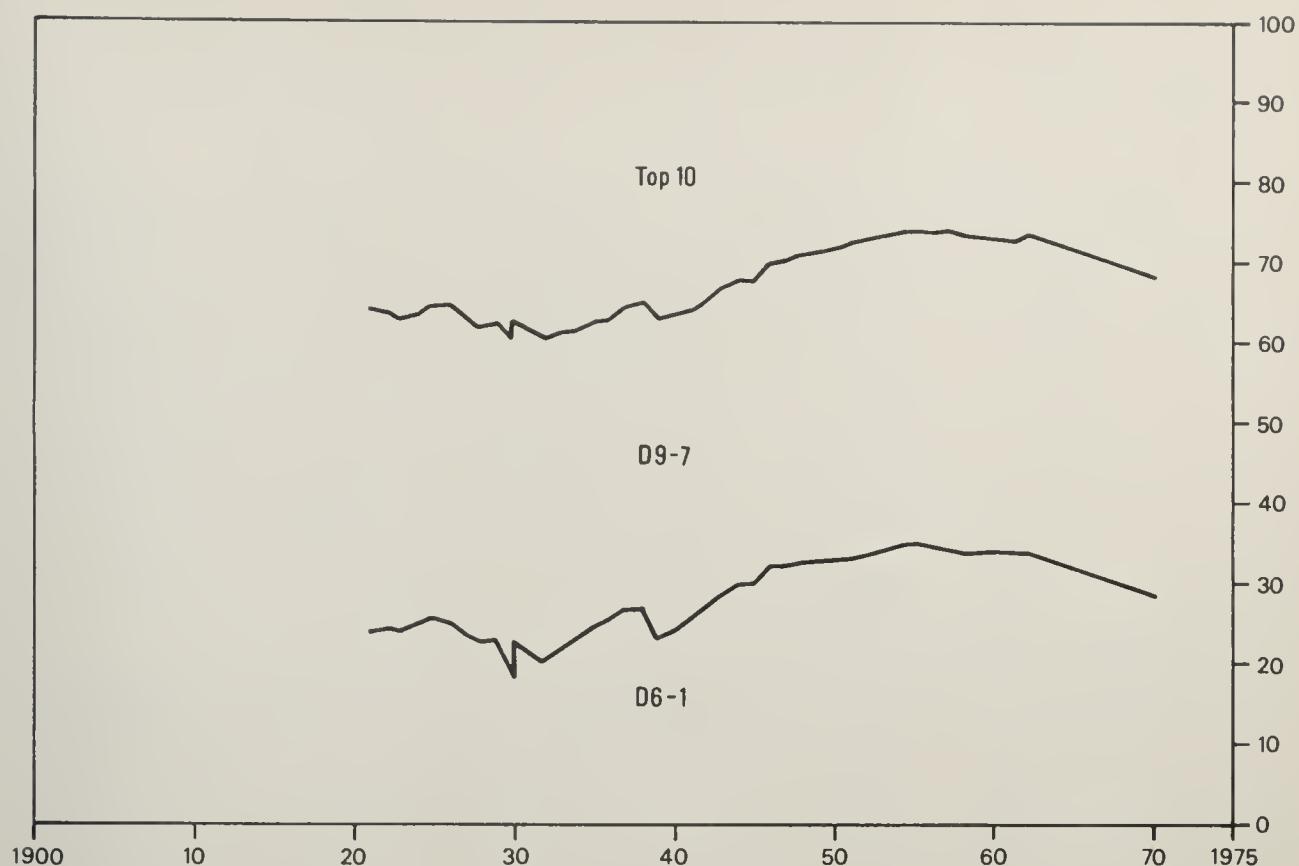

Coverage: Coverage ratios show the total number of economically active income recipients as % of the conceptually adjusted labour force (previous to 1939 incl. renters).

Adjustment for
improper cov.: In the case of insufficient coverage inclusion of the missing units within the lowest income class and adjustment of the lowest income limit to Kr. 1.

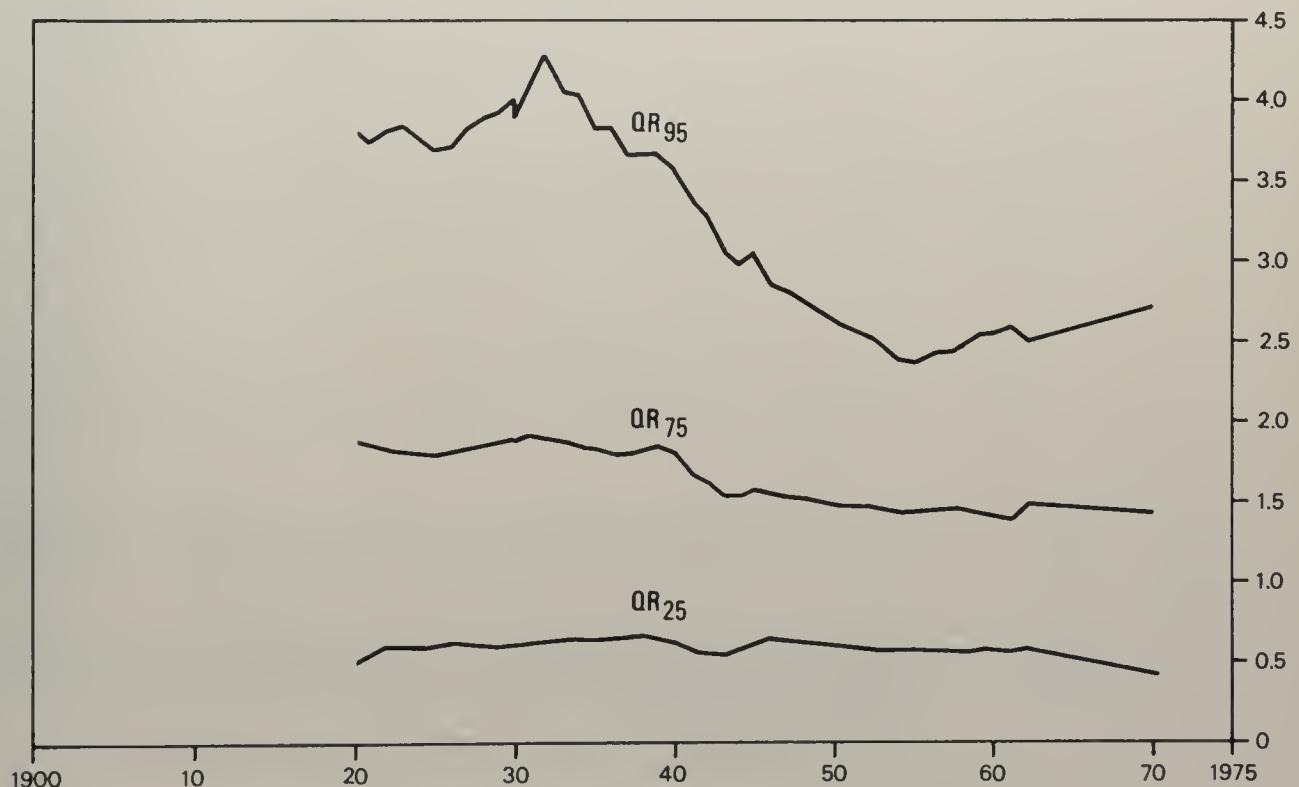

a) For fractiles below the coverage ratio estimates are crude.
b) For quantiles below the coverage ratio estimates are crude.
c) Prior to 1938 estimates are strongly dependend on method of interpolation.
d) Individual taxation; conceptually not comparable to previous years.
e) Inclusive of economically inactive tax units.
f) Refers to gross income; conceptually not comparable to previous years.
g) Population census after exclusion of economically inactive income recipients.
h) Population census before exclusion of economically inactive income recipients.

Population:	
1974e)-1971e)	Income recipients up to age 64.
1974f)-1971f)	Employees and workers.
1971 - 1945	Labour force (excl. of the category 'Unknown'). Post to 1971 distribution data by status of employment have not been available to us.
Income:	Assessed income.
Coverage:	Coverage ratios show the total number of income recipients as % of the respective population concepts.
Adjustment for improper cov.:	In the case of insufficient coverage inclusion of the missing units within the lowest income class and adjustment of the lowest income limit to Mk. 1; in the case of excessive coverage exclusion of the excessive units from the lowest income class and corresponding adjustment of the lowest income limit.
a)	For fractiles below the coverage ratio estimates are crude. Estimates for 1929 and 1922 are very crude and certainly exaggerate inequality.
b)	1974-1962 in new Finnish Marks.
c)	For quantiles below the coverage ratio estimates are crude.
d)	Prior to 1955 estimates are strongly dependend on the method of interpolation. Cf. note a)
e)	Income recipients up to age 64.
f)	Employees and workers only.

Germany

West Germany (1974-1950)

Sources:	Wage-statistics, income assessment statistics and various articles in <i>Wirtschaft und Statistik</i> , ed. by Statistisches Bundesamt.
Population:	a) The series on employment incomes in principle refers to employees and workers, largely exclusive of family workers. Cf. notes on improper coverage. b) The series on personal incomes in principle refers to the total labour force, including renters and most of the pensioners. Recipients of old-age pensions are included only to a small degree. Cf. notes on improper coverage.
Income:	Gross incomes.
Coverage:	Coverage ratios show the total number of income recipients on which reported distributions are based as % of employees and workers excl. of family workers, resp. as % of total labour force.
Adjustment for improper cov.:	No adjustments, since improper coverage is not due to the existence of an income limit, but to insufficient coverage of tax returns (especially with respect to low incomes in general and agricultural incomes in particular).

German Empire

Sources:	<i>Wirtschaft und Statistik</i> , 1939, published by Statistisches Reichsamt.
Population:	Total labour force exclusive of family workers and unemployed plus pensioners. Multiple inclusions as a result of the particular taxation system (separate assessment of labour incomes and incomes from other sources) have been excluded by the Statistical Office.
Income:	
1932-1938	Gross incomes before any deductions and allowances;
1930-1913	mixed definitions (wage-earners in principle are included with their incomes after basic allowances; persons subject to the assessment tax are included with their gross incomes).
Coverage:	Coverage ratios show the total of income recipients on which the reported distributions are based as % of total labour force exclusive of family workers.
Adjustment for improper cov.:	No adjustment could be made to include the unemployed. Agricultural incomes are included also for periods during which they had not been liable to tax.

Prussia

Sources:	J. Müller and S. Geisendorfer, <i>Die Einkommensstruktur in verschiedenen deutschen Ländern 1874-1912</i> , Berlin 1971. Tax statistics published by the Prussian Statistical Bureau.
Population:	Labour force and renters.
Income:	Gross incomes.
Coverage:	The coverage ratios show the total number of taxed units as % of the total labour force after exclusion of family workers. The Prussian labour force has roughly been estimated by applying the activity rates for the German Empire (after exclusion of family workers) to the Prussian population figures. Family workers have been excluded because they form the major part of joint taxations.
Adjustment for improper cov.:	Because of the imprecise and varying assessment rules and administrative procedures no adjustments possible.

Saxony

Sources: A. Jeck, Wachstum und Verteilung des Volkseinkommens, Tübingen 1970. Coverage ratios own calculations.

Population: Labour force.

Income: Gross income.

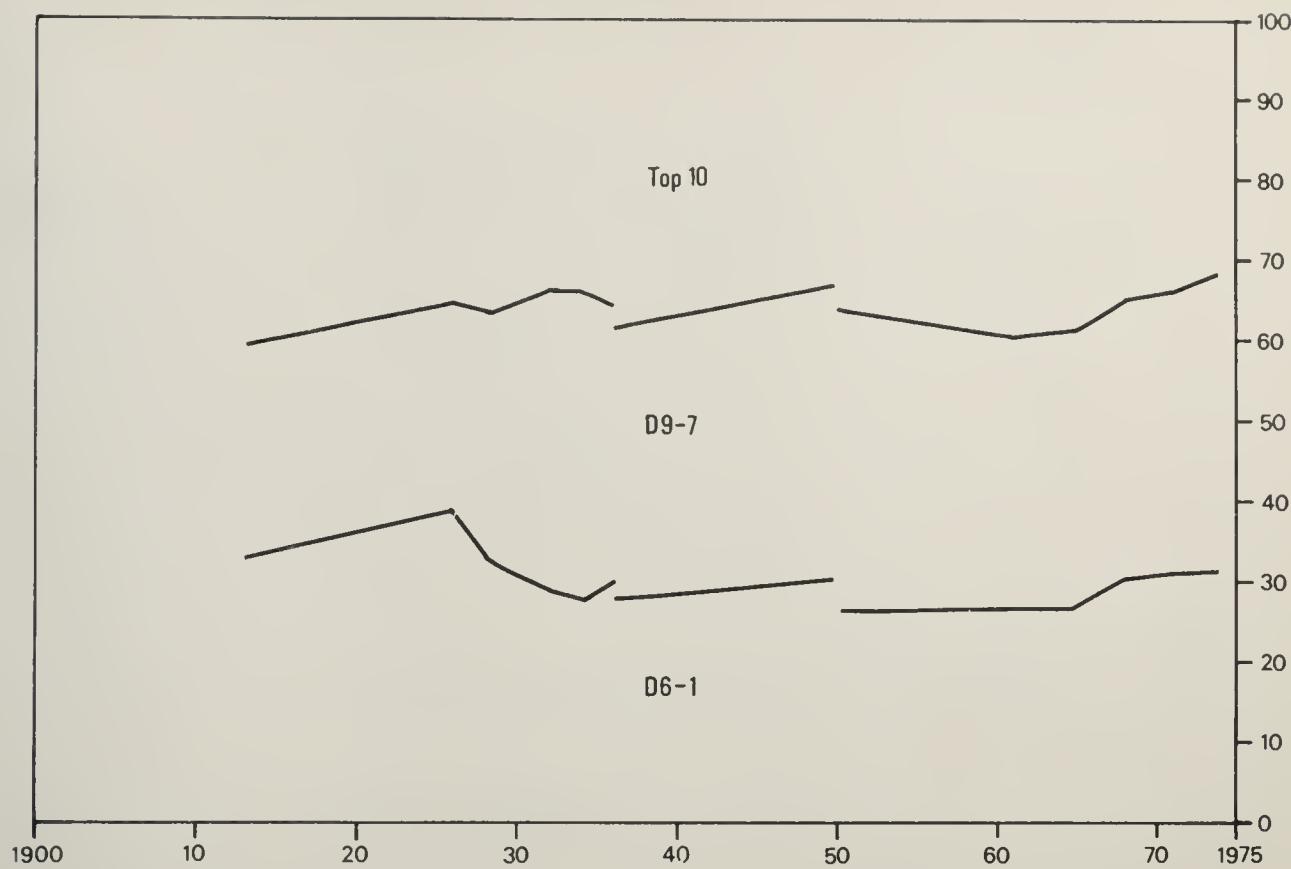

Coverage: The coverage ratios show the total number of assessed persons (incl. those below the tax threshold) as % of the labour force of Saxony.

Adjustment for None (insufficient coverage not due to the existence of an income limit).
improper cov.:

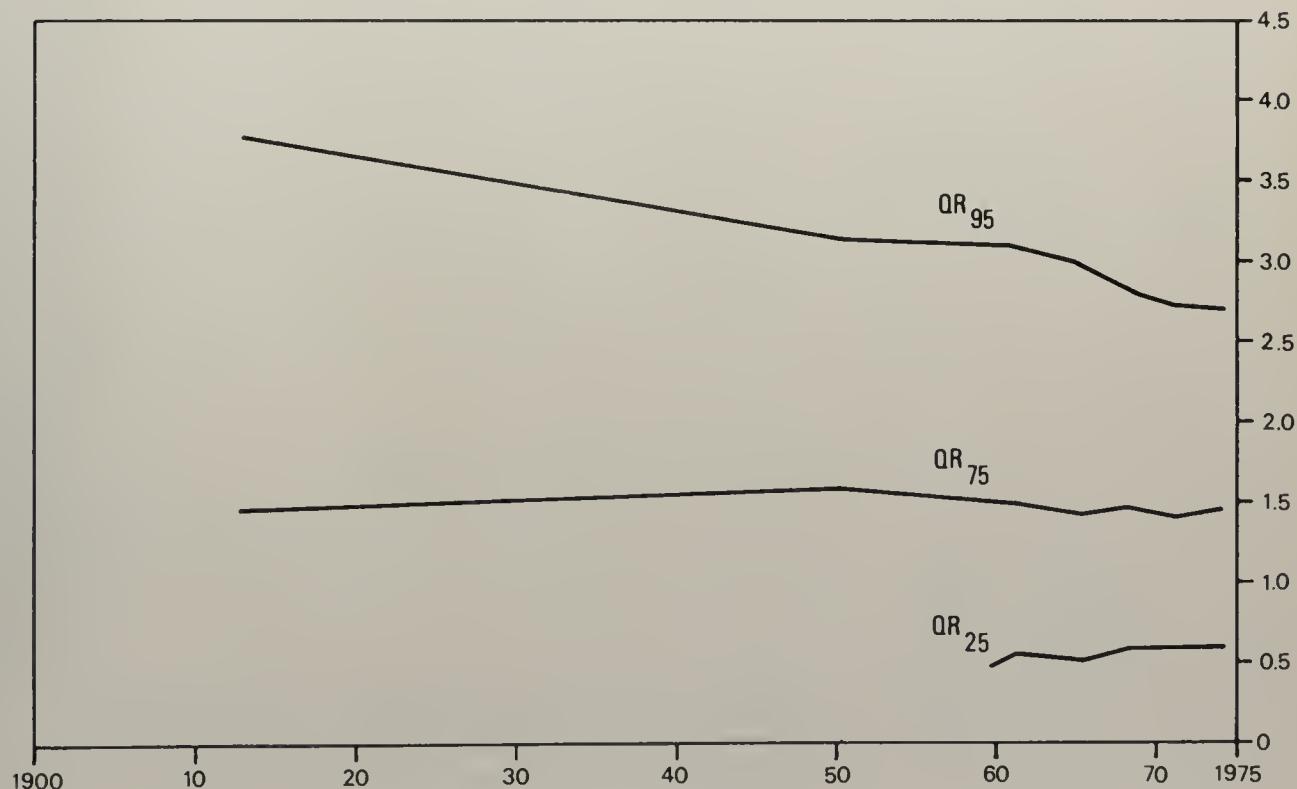

- a) Conceptually comparable to the 1939-distribution. Respective distributions refer, however, to different territories.
- b) Including unemployed and excluding pensioners and recipients of old-age benefits. Conceptually comparable to 1950.
- c) Crude estimate. Cf note on coverage.
- d) Income shares of the top 5% only.

Sources: Tax statistics.

Population: Labour force (excl. of category 'unknown').

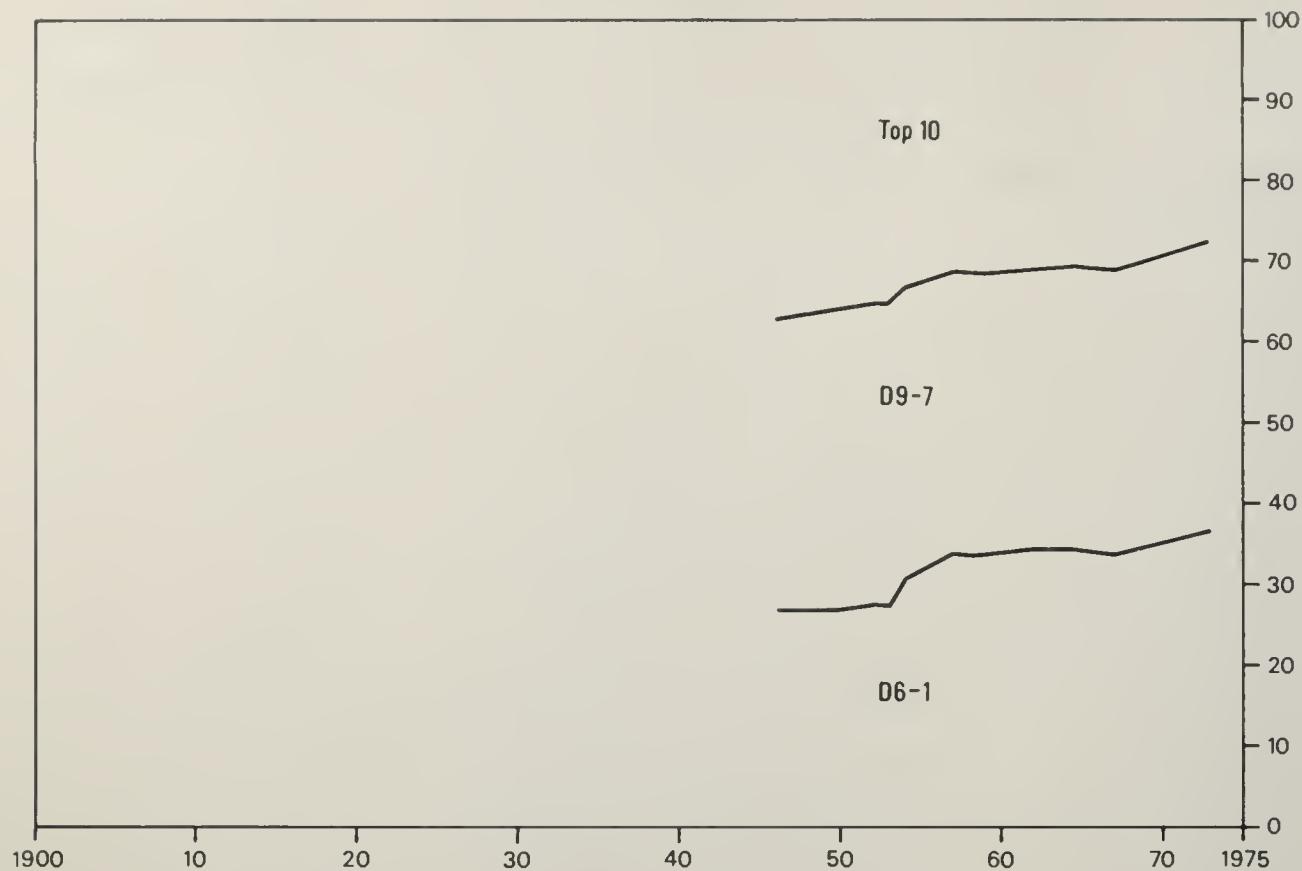

Income: Total taxable income.

Coverage: Coverage ratios show the total number of economically active income recipients as % of the conceptually adjusted labour force.

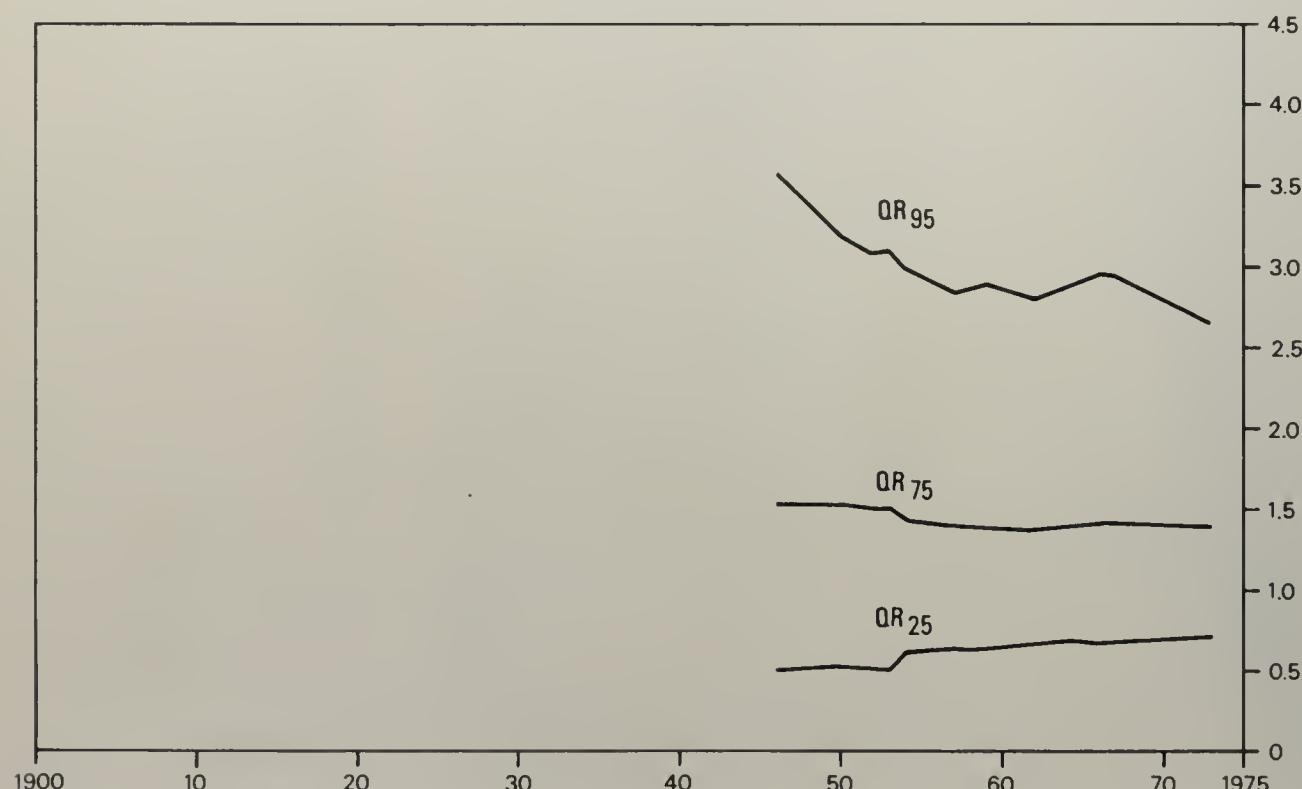

Adjustments for Exclusion of all economically inactive income recipients.

Sources: Kiaer, A. et al, Socialstatistik, Kristiania 1898;
Population censuees (1930, 1910);
Tax statistics.

Population:

1975-1967 All income recipients irrespective of source/size of income.

1967-1948 Total labour force exclusive of seamen.

1929, 1913, 1910 All taxpayers listed in tax enrollments.

1911 All income recipients irrespective of source/size of income.

1891 Representative sample of male labour force (cf. Kiaer).

Income: Income after allowable deductions, reliefs and personal allowances (taxed income).

Coverage: Coverage ratios show the total number of tax units as % of the labour force adjusted to the prevailing tax unit concepts.

Adjustments for improper coverage:

1929-1891 No adjustments.

1975-1943 Exclusion of excessive units from lowest income class and corresponding adjustment of the lowest income limit; inclusion of missing units within the lowest income class and adjustment of the lowest income limit to 1 Kr.

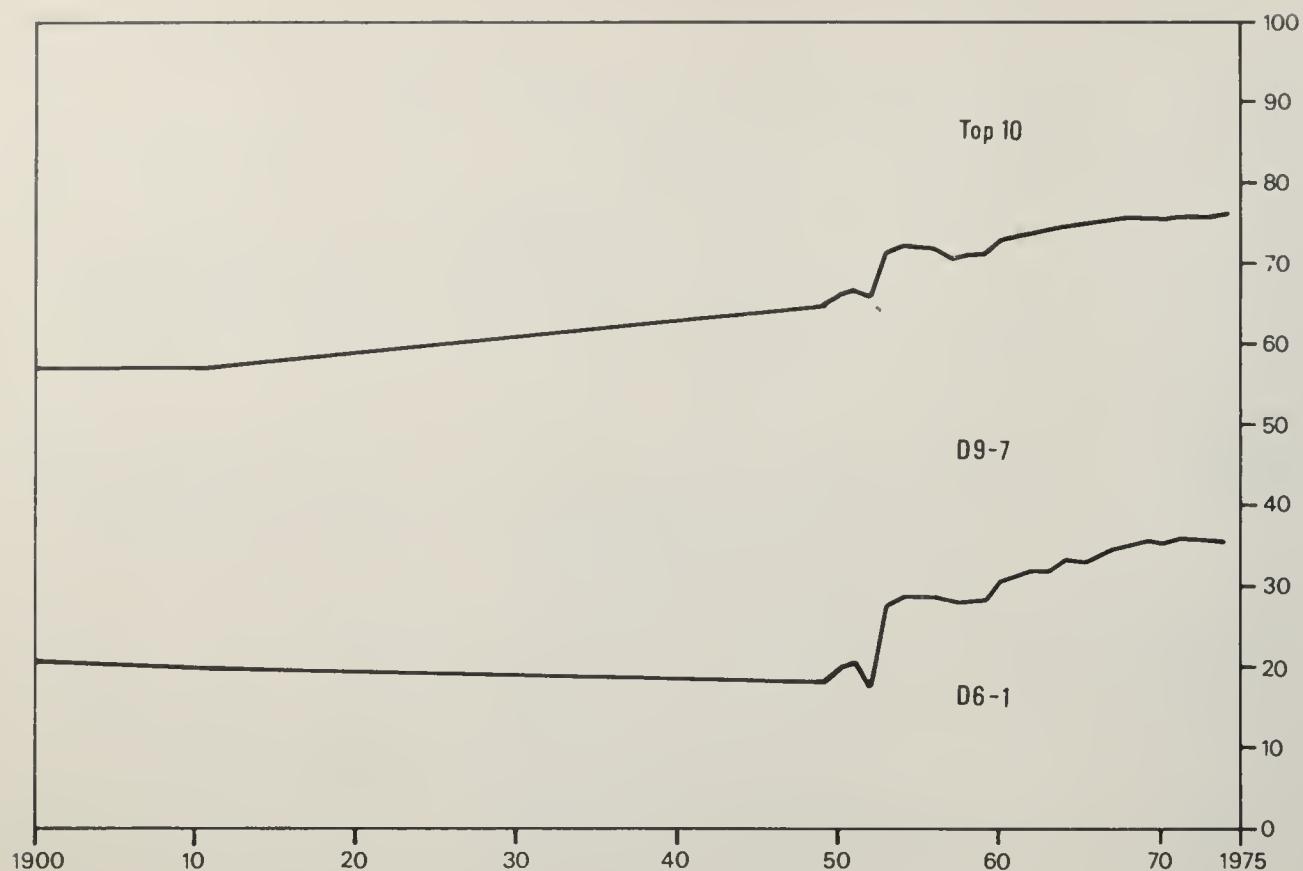

a) Unadjusted tax data covering recipients with taxed income of 1 Kr and over.

b) Population census.

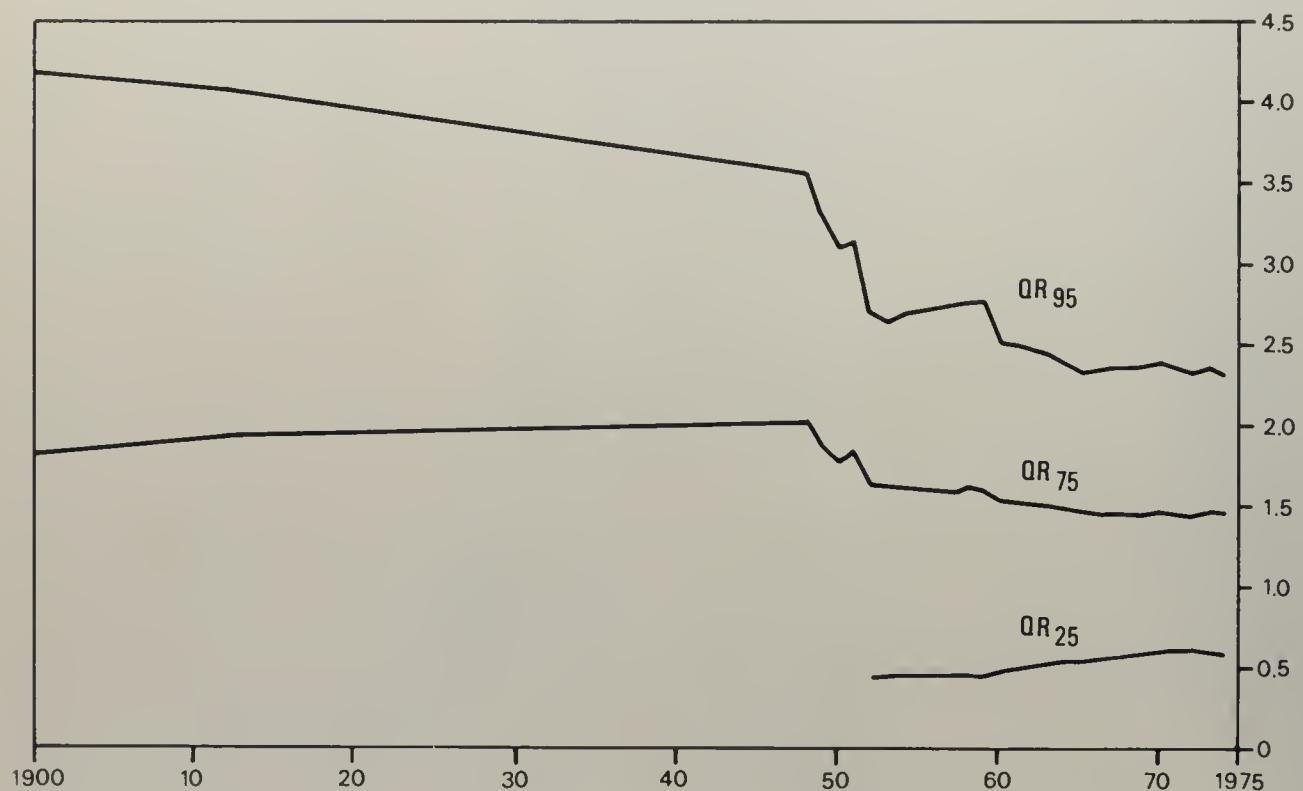

c) Representative sample for active males.

LABOUR DISPUTES

This chapter presents basic data on the development of labour conflicts in terms of their frequency, size and duration. Time series are given for the following three main indicators: the number of labour conflicts, the number of workers participating in them, and the number of man-days lost due to them. These statistics are presented in the form of national aggregate data, as absolute figures and relative to the dependent labour force.

In most European countries, official statistics on labour conflicts became available around the turn of the century. This must be seen in the context of an increasing incidence of strikes at that time which in turn was largely the result of an improving organization of the working class. Frequently, it was a parliamentary commission which initiated the regular collection of official strike data. In some countries, non-official strike statistics, usually collected by trade unions or employers' associations, exist alongside the official ones. We have utilized these 'private' statistics only in exceptional cases, and when government-produced data are not available.

In the initial phase strike statistics developed rapidly, reaching the highest level of sophistication around World War I. Many of the detailed series on specific characteristics of labour conflicts end in the 1930s, at a time when the Great Depression led to a reduction of trade union power and strike incidence. After World War II strike statistics remained comparatively poor. This may be explained to some extent by the decreasing strike activity in most European countries, a development which led many observers to speak of a 'withering away of the strike'. Since the late 1960s, we know that this view of industrial relations was premature, but the widespread increase in labour conflicts has not led so far to any decisive improvement in strike statistics.

In dealing with these statistics, attention must be paid to the difference in the definition of labour conflicts adopted by the statistical agencies: how a single conflict is identified, how its participants are counted and how its duration is measured.

In principle, a strike is any collective work stoppage of dependent workers/employees. A first problem of this definition refers to the status of 'dependence'. There are cases of formally independent, self-employed persons (e.g. tenants of petrol stations or small shopkeepers) who use collective work stoppages as a weapon against private enterprises or public agencies upon which, in practice, they may be very much dependent. For the sake of conceptual clarity, these collective conflicts have not been included. They are also a relatively new phenomenon and not very relevant in terms of national strike statistics.

A second problem is whether collective work stoppages, in order to be called strikes, must have strictly 'economic' goals, i.e. goals which can be attained in negotiations with employers. As we know, many strikes contain a 'political' element in the sense that they are used to influence government action. This political element is more important in some countries/periods than in others, and exclusion of 'political strikes' would seriously reduce comparability. Furthermore, there is no possibility, on the basis of official statistics, to consistently distinguish between 'economic' and 'political' objectives of work stoppage. We have therefore included all strikes, even when their political character was openly declared.

A third more general problem refers to the distinction between strikes and lock-outs. First of all, there is a practical problem to draw a clear line between these two forms/sides of labour conflicts, because one may easily lead to the other. In addition, data on lock-outs are often not collected or they are not given separately in official statistics. Furthermore, in more recent times lock-outs may also be prohibited. At present, no distinction is usually made between strikes and lock-outs, both being counted as labour conflicts.

If a conflict involves a number of different establishments, is it identified as one strike or several? Disputes affecting several establishments may be counted as one case if they break out simultaneously, if they have a common purpose or if they are organized by one person or one organization. Apart from cases

vary greatly, leading to rather different aggregate numbers of strikes. Some countries therefore try to avoid these difficulties by counting only establishments involved in strikes and not the strikes themselves.

The aggregate number of strikes may be influenced by two further variations in operational criteria. One of them refers to the question of whether a minimum number of strikers and/or working-days lost is required. In more recent periods, this is a frequent procedure. Usually, a collective work stoppage is only counted as a strike if at least 100 workers are involved and/or 100 working-days are lost. This leads to a considerable underestimation of the frequency of strikes, as shown in empirical studies, especially in countries/periods in which small-scale and short-term strikes are relatively more frequent. Annual aggregate figures may furthermore be influenced by the method of counting strikes which begin in one year and end in the next. They may be counted only once, in the year when they start or end, or they may be counted in each year that disputes are in progress.

The number of strikes is an important measure of strike activity, but of course the number of strikers involved in each conflict may vary greatly. In counting participants one is confronted with two problems. The first concerns the distinction between workers who are directly involved in strikes, and those only indirectly involved who are much more difficult to enumerate. Usually, these are only included for establishments where conflicts took place. A second problem is whether the average or the maximum number of participants in a labour conflict is taken.

There is no general pattern in the long-term development of strikes except in their duration: strikes tend to last for shorter periods of time. Duration is an indicator of both the intensity of conflicts and the organizational capacity of workers to maintain solidarity. The simplest overall measure of duration is the number of working-days lost in conflicts. Caution must be applied when interpreting these data because of two problems. First, some big conflicts may distort the picture. Second, the method by which the number of working-days lost is obtained varies across countries and periods. They may be counted for each day and participant or calculated by multiplying the duration of the conflicts in terms of working-days by the number of participants. In the latter case, a strike may be said to last from its official declaration to its official end. However, the duration may also be measured from the time when the first workers lay down their tools to the time when the first workers go back on the job.

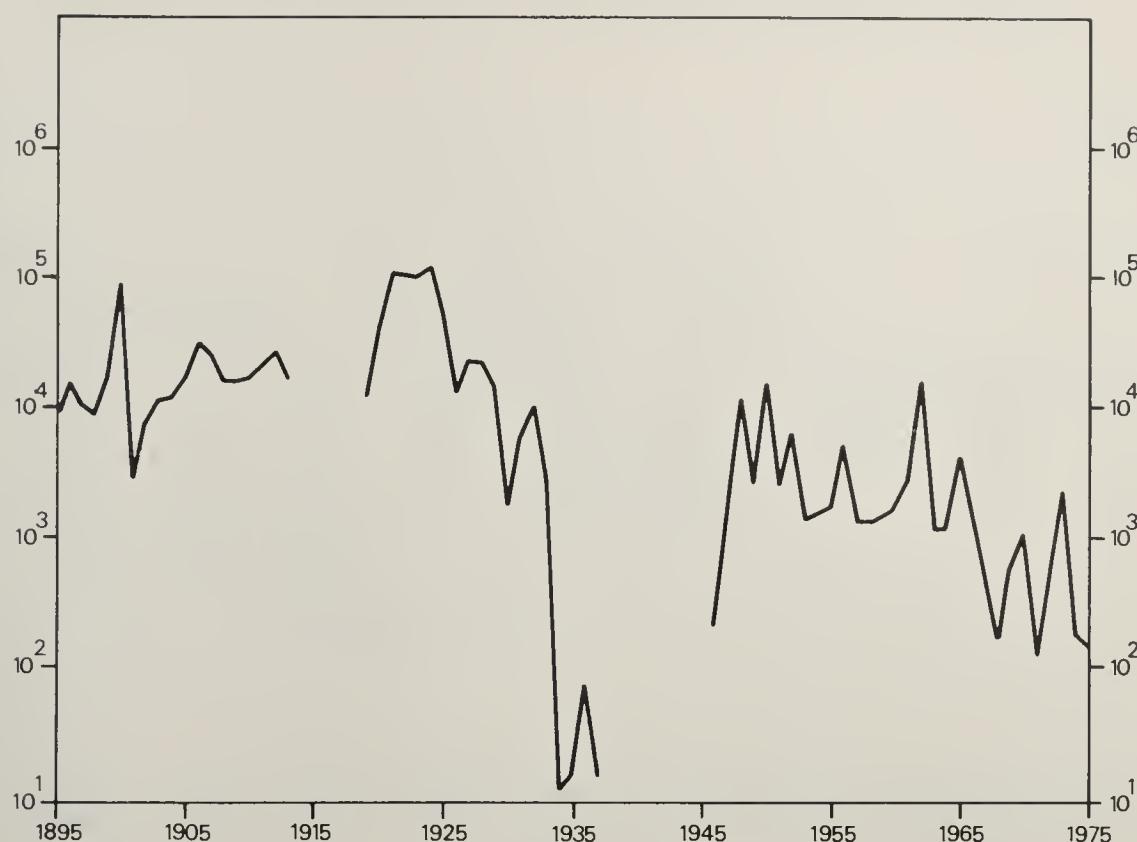

Major variations in the definition and measurement of labour conflicts are documented in the footnotes to the following tables. For each country, in alphabetical order, two tables are given, one with raw data and one with indicators. The first table contains (1) the number of conflicts (strikes, lock-outs, and total conflicts), (2) the number of participants (strikers, lock-outers, indirectly involved persons, and total participants), and (3) the number of working-days lost (by strikers, lock-outers, indirectly involved persons, and by total participants).

In the second table two types of indicators are given: firstly, indicators which define the shape of the typical strike in a given year, average size (strikers per strike) and average duration (working-days lost per strike and striker); secondly, indicators of the aggregate strike activity which take into account the great variations in the 'potential strike population', namely the dependent labour force. They give the number of conflicts, participants, and working-days lost per 100,000 non-agricultural wage-earners. Figures of the dependent labour force have been derived from the census data in Chapter 7. Census figures of the dependent labour force, expressed as percentage of the total population, have been interpolated for the intercensus years (except for the years around World War I and II for which the percentages have been extrapolated forwards and backwards). The percentages then have been multiplied by the total population figures given in Chapter 1. The tables are preceded by 13 graphs which show the development of the volume of labour disputes.

a) From 1945 data on disputes and persons involved are reported for the given year, whereas data on man-days lost refer to 'labour disputes in progress'; up to 1940 all data refer to labour disputes terminated in the given year.

b) Excluding 888 strikes against social policy legislation; no data on man-days lost collected during a three-month period.

c) Data on lock-outs not available prior to 1906.

d) Data on man-days lost not available prior to 1927.

e) Very incomplete data for 1890-95 collected by the General Council of the Belgian Labour Party.

a) From 1943 data on labour disputes collected only in cases with more than 100 man-days aggregate loss; method of collection changed in 1943; for purpose of comparison, additional data, collected according to the old method, provided for several years after this change.

b) Up to 1925 data on participation and man-days not reported for all labour disputes (see N); separate figures for strikes and lock-outs not available prior to 1911.

c) Labour disputes changing from strikes to lock-outs, or vice versa.

a) From 1971 new method of collection; data for previous years not strictly comparable.

b) No data on 'persons indirectly involved' available between 1945 and 1970; however, total man-days lost reported for directly and indirectly involved.

c) Up to 1906 data are based on private collection; data on participants not available for all disputes (see N).

d) Including the general strike in 1917.

a) Including Algeria from 1890 to 1962, and Alsace-Lorraine from 1919; data up to 1889 drawn from Edward Shorter and Charles Tilly, *Strikes in France*. Cambridge, Cambridge University Press, 1974.

b) No data collected.

c) Including ca. 1,000,000 man-days lost in a general strike.

a) Up to 1968 drawn from a data collection based on a re-analysis of archive-material in the Federal Statistical Office. These figures are by and large one third higher than the official data, since the official definition excluded labour disputes with less than 100 participants or less than 100 aggregate man-days lost. From 1969 data drawn from official statistics; number of disputes not available.

a) Including man-days lost indirectly in strikes and lock-outs.

b) Including political strikes from 1919 to 1925.

c) Up to 1898 data for Prussia and Bavaria only; from two statistical sources differing in method.

d) Data drawn from private data collection by Walter Steglich, based on newspapers.

- a) Labour disputes prohibited after 1924; from 1881 including strikes in the agricultural sector which account for a large portion of the total strike activity.
- b) Data on persons indirectly involved only collected from 1886 to 1901.
- c) Data on man-days lost collected only from 1894 to 1914. Data on man-days lost in agricultural strikes not available for 1904 and 1905.

a) Up to 1920 data on participants and man-days lost estimated by the Statistical Office, partially based on private collections; from 1921 data collected by the Statistical Office.

b) Including labour disputes counted in both years when they begin in one year and are still in progress the following year.

c) Labour disputes beginning in the given year.

d) Data collected by the Norwegian Trade Union Federation.

e) Data collected by the Norwegian Federation of Employers' Associations.

a) From 1951 data on participants and man-days lost not broken down by strikes and lock-outs, except in 1971;
up to 1950 data broken down by strikes, lock-outs and mixed disputes (i.e. strikes turning into lock-outs
or vice versa).

							1893

y) Northern Ireland excluded from total labour force; share of labour force was held constant at 1914 level for 1915 to 1918, and was interpolated between 1931 and 1946.

A full documentation of all data presented in our handbook would certainly go beyond the limits even of two bulky volumes — and beyond the reasonable limits of a commercial publishing house. Without documentation, however, a data collection of this kind would of course be much less useful. In the analysis of the long-term changes of the European societies, we need a broad data basis which can be improved step by step. And this means documentation. Given the limits of space, it must be a separate documentation.

In the preface to the first volume, I promised a „separate documentation which will be available through the ICPSR at Ann Arbor for the American user and through the Zentralarchiv in Cologne for Europe“. We hold to our promise even though this service for a wider public is a thankless task for persons working on a project basis.

In the course of 1986, altogether eleven data sets will become available including either a machine-readable or typed documentation.

No. of data set	Name of data set	Type of documentation
1	Population structure	machine-readable
2	Labourforce	machine-readable
3	National product	machine-readable
4	Income inequality	machine-readable
5	Labour disputes	machine-readable
6	Public revenues	typed
7	Public expenditure	typed
8	Governmental personnel	typed
9	Public education	typed
10	Income maintenance	typed
11	Population movements	typed

With these eleven data sets, 12 out of 19 chapters of the two volumes will be fully documented, i.e. Chapters 5 and 7–10 in Volume I and Chapter 1–2 and 5–9 in Volume II. The remaining 7 chapters contain only a small proportion of all data. These data will not be made available in machine-readable form nor will they be documented in a form which could be distributed.

The data in Chapters 1 and 2 of Volume I and Chapters 3 and 4 of Volume II have all been drawn from official population census publications and are documented in handwritten form. This documentation will not be generally made available, but we hope to publish a bibliography of census publication in the near future.

For Chapter 3 and 4 in Volume I, we have relied mainly on two sources: Tom Mackie and Richard Rose, *The International Almanach of Electoral History*. London, Macmillan, 1974, and Klaus von Beyme, *Die parlamentarischen Regierungssysteme Europas*. München, Piper, 1973. There is a separate typed documentation of the data on the extension of the suffrage by Jürgen Kohl, but the documentation of the other sources as well as of our classifications, calculations and estimates is only in handwritten form and will not generally be made available.

The data in Chapter 6 of Volume I are from David Singer at the University of Michigan, Ann Arbor. For a documentation see: Correlates of War Project, 'Instructions for Collecting Military Personnel Data', Mental Health Research Institute, University of Michigan, July 1971.

In general, we have relied almost exclusively on published official statistics. These sources will be found in the typed or machine-readable documentation of the eleven data sets. A history and bibliography of European official statistics has been published by Peter Flora in *Current Sociology* 23, 1975, No. 2. In some cases, however, we have used secondary sources for more important parts of our data collection. These sources are given here. They in which they have been used can be found in the documentations.

Government personnel (Vol. I, Chapter 5)
